Heart Institute, Asan Medical Center

Why We Need FFR in LM Disease?

- Inaccuracy of Coronary Angiography
- Lack or Low Spatial Resolution of Non-Invasive Functional Study
- FFR guided PCI in LMCA Also Showed Favorable Outcomes

Major Randomized Studies in LM

ORIGINAL ARTICLE

Outcomes in Patients With De Novo Left Main Disease Treated With Either Percutaneous Coronary Intervention Using Grafts or Coronary Artery Bypass Surgery

Acute Myocardial Infarction and Death in Coronary Artery Disease

Maria E. Bittner, MD; Ted E. Feldman, MD; Paul D. Harrington, MD; Daniel S. Lee, MD; David A. Pocock, PhD; Michael J. Rosenthal, MD; Michael J. Steiner, MD; Michael J. Tsang, MD; Michael J. Whalen, MD; and the Investigators of the GRAFT Trial

Background: The optimal treatment for de novo left main coronary artery disease remains controversial. Percutaneous coronary intervention (PCI) using drug-eluting stents has been shown to be effective in some patients. Coronary artery bypass surgery (CABG) is considered the standard of care for left main disease.

Objectives: The goal of this study was to compare the outcomes of PCI using drug-eluting stents versus CABG in patients with de novo left main disease.

Methods: This was a prospective, multicenter, randomized trial comparing PCI using drug-eluting stents versus CABG in 201 patients with de novo left main disease. The primary end point was a composite of death, myocardial infarction, and stroke at 1 year.

Results: At 1 year, the rate of the primary end point was 3.2% in the PCI group versus 11.8% in the CABG group ($P = .03$). The rate of all-cause mortality was 3.2% in the PCI group versus 11.8% in the CABG group ($P = .03$). The rate of myocardial infarction was 1.5% in the PCI group versus 5.0% in the CABG group ($P = .10$). The rate of stroke was 0.5% in the PCI group versus 1.5% in the CABG group ($P = .10$). The rate of repeat revascularization was 1.5% in the PCI group versus 1.5% in the CABG group ($P = .99$).

Conclusion: In this study, PCI using drug-eluting stents was associated with a lower rate of the primary end point than CABG in patients with de novo left main disease. (J Am Coll Cardiol 2008;51:551–558)

Randomized Comparison of Percutaneous Coronary Intervention With Sirolimus-Eluting Stents Versus Coronary Artery Bypass Grafting in Unprotected Left Main Stem Stenosis

Enno Boudriot, MD,* Holger Thiele, MD,* Thomas Walther, MD,† Christoph Liebetrau, MD,* Peter Pachaly, MD,‡ Tilman Röhm, MD,‡ Peter Reindel, MD,§ Hans-Jürgen Meier, MD,||

Background: Coronary artery bypass grafting (CABG) is the standard of care for unprotected left main stem stenosis. Percutaneous coronary intervention (PCI) using drug-eluting stents has been shown to be effective in some patients.

Objectives: The aim of this study was to compare the outcomes of PCI using sirolimus-eluting stents versus CABG in patients with unprotected left main stem stenosis.

Methods: This was a prospective, multicenter, randomized trial comparing PCI using sirolimus-eluting stents versus CABG in 201 patients with unprotected left main stem stenosis. The primary end point was a composite of death, myocardial infarction, and stroke at 1 year.

Results: At 1 year, the rate of the primary end point was 3.2% in the PCI group versus 11.8% in the CABG group ($P = .03$). The rate of all-cause mortality was 3.2% in the PCI group versus 11.8% in the CABG group ($P = .03$). The rate of myocardial infarction was 1.5% in the PCI group versus 5.0% in the CABG group ($P = .10$). The rate of stroke was 0.5% in the PCI group versus 1.5% in the CABG group ($P = .10$). The rate of repeat revascularization was 1.5% in the PCI group versus 1.5% in the CABG group ($P = .99$).

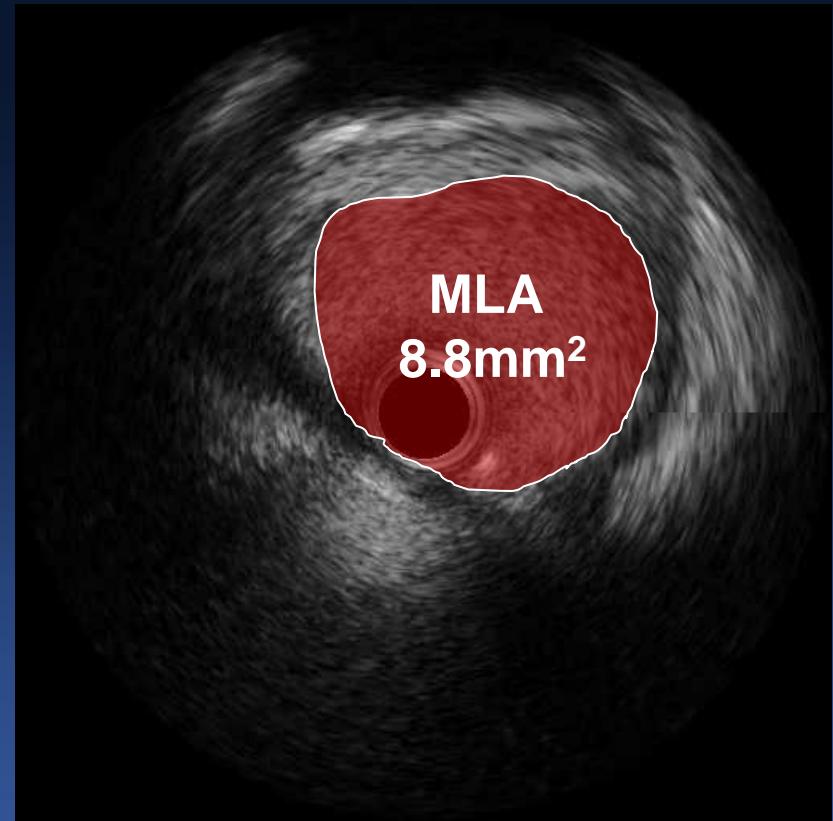

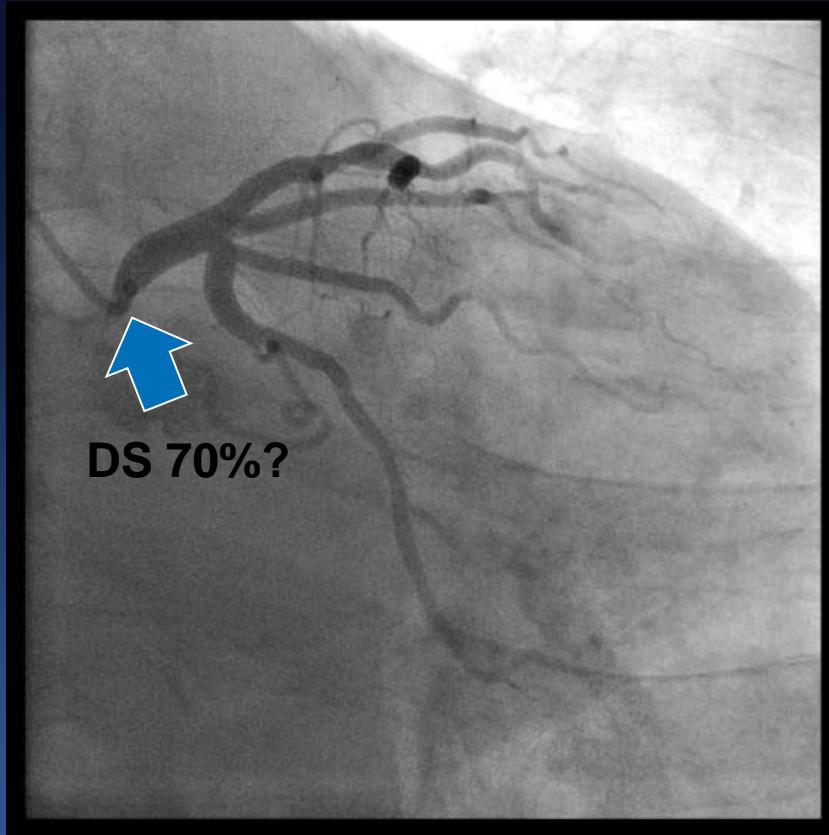

Conclusion: In this study, PCI using drug-eluting stents was associated with a lower rate of the primary end point than CABG in patients with unprotected left main stem stenosis. (J Am Coll Cardiol 2011;57:551–558)

Patients age 18 to 80 years with stenosis ($\geq 50\%$) of the ULM with or without additional multivessel coronary artery disease were included in this multicenter study. Patients had

Background CABG is considered the standard of care for treatment of ULM. Improvements in percutaneous coronary intervention (PCI) with use of drug-eluting stents might lead to similar results. The effectiveness of drug-eluting stenting versus surgery has not been established in a randomized trial.

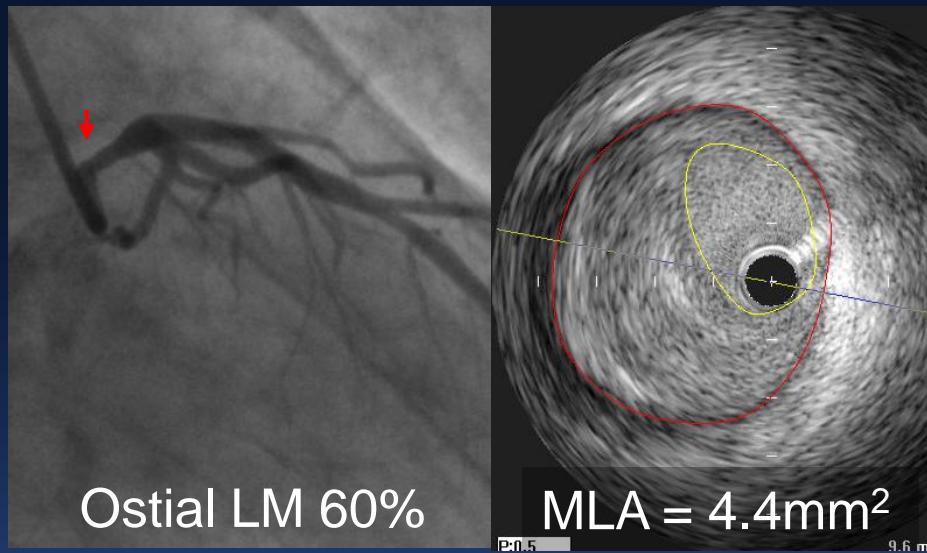

Methods In this prospective, multicenter, randomized trial, 201 patients with ULM disease were randomly assigned to

Why We Need FFR in LM Disease?

- Inaccuracy of Coronary Angiography
- Lack or Low Spatial Resolution of Non-Invasive Functional Study
- FFR guided PCI in LMCA Also Showed Favorable Outcomes

Therefore, We Have To Measure LM FFR

How Can We Implement FFR in LM stenosis?

LMCA Anatomy

(A) Ostial/Shaft

(B) Bifurcation

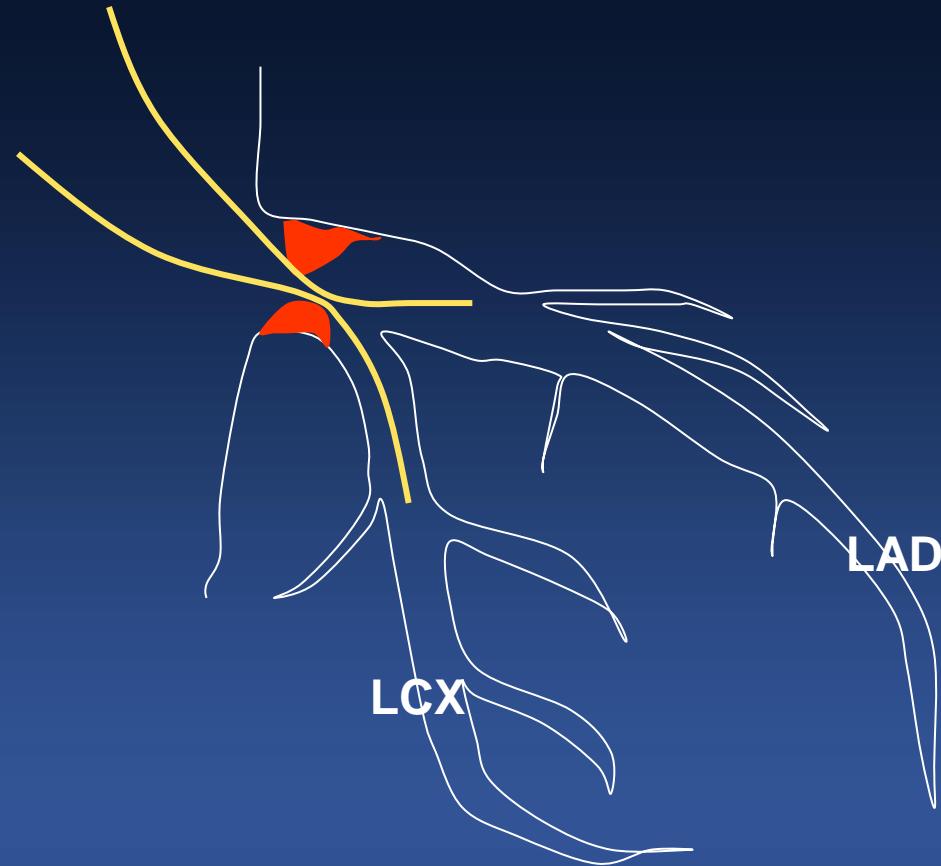

(C) LM with distal Dz

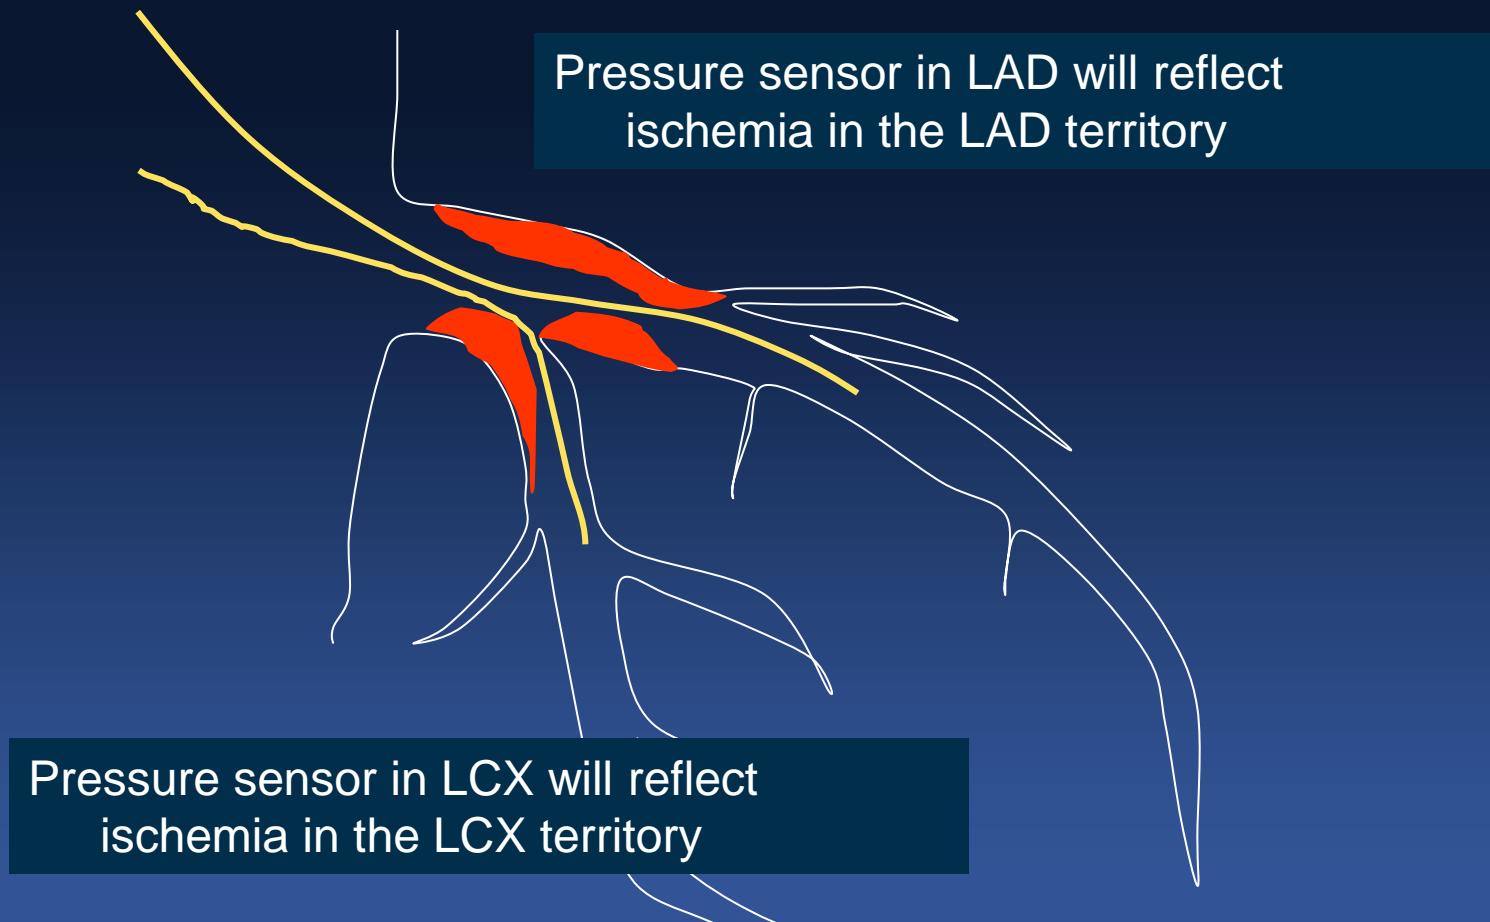

For the Undetermined, Intermediate Ostial and Shaft LM Lesion,

Theoretically, **LAD FFR = LCX FFR = LM FFR**

For the Intermediate LM Bifurcation Lesion,

LAD FFR ≠ LCX FFR ≠ LM FFR

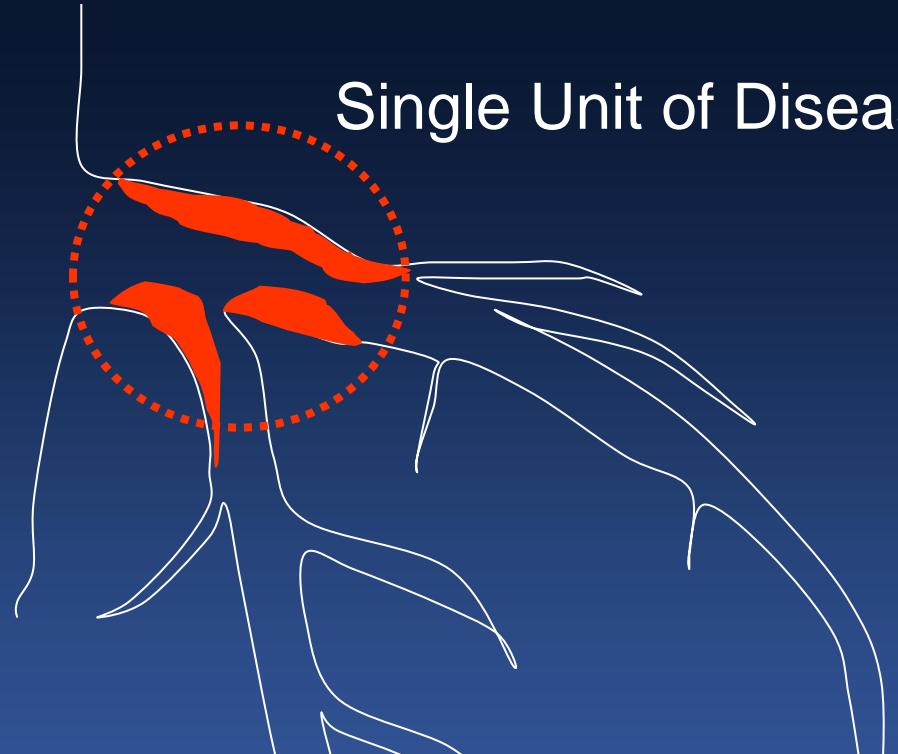

For the Intermediate LM Bifurcation Lesion,

If any of FFR in LAD or LCX<0.80

Main Concern is Just to Determine

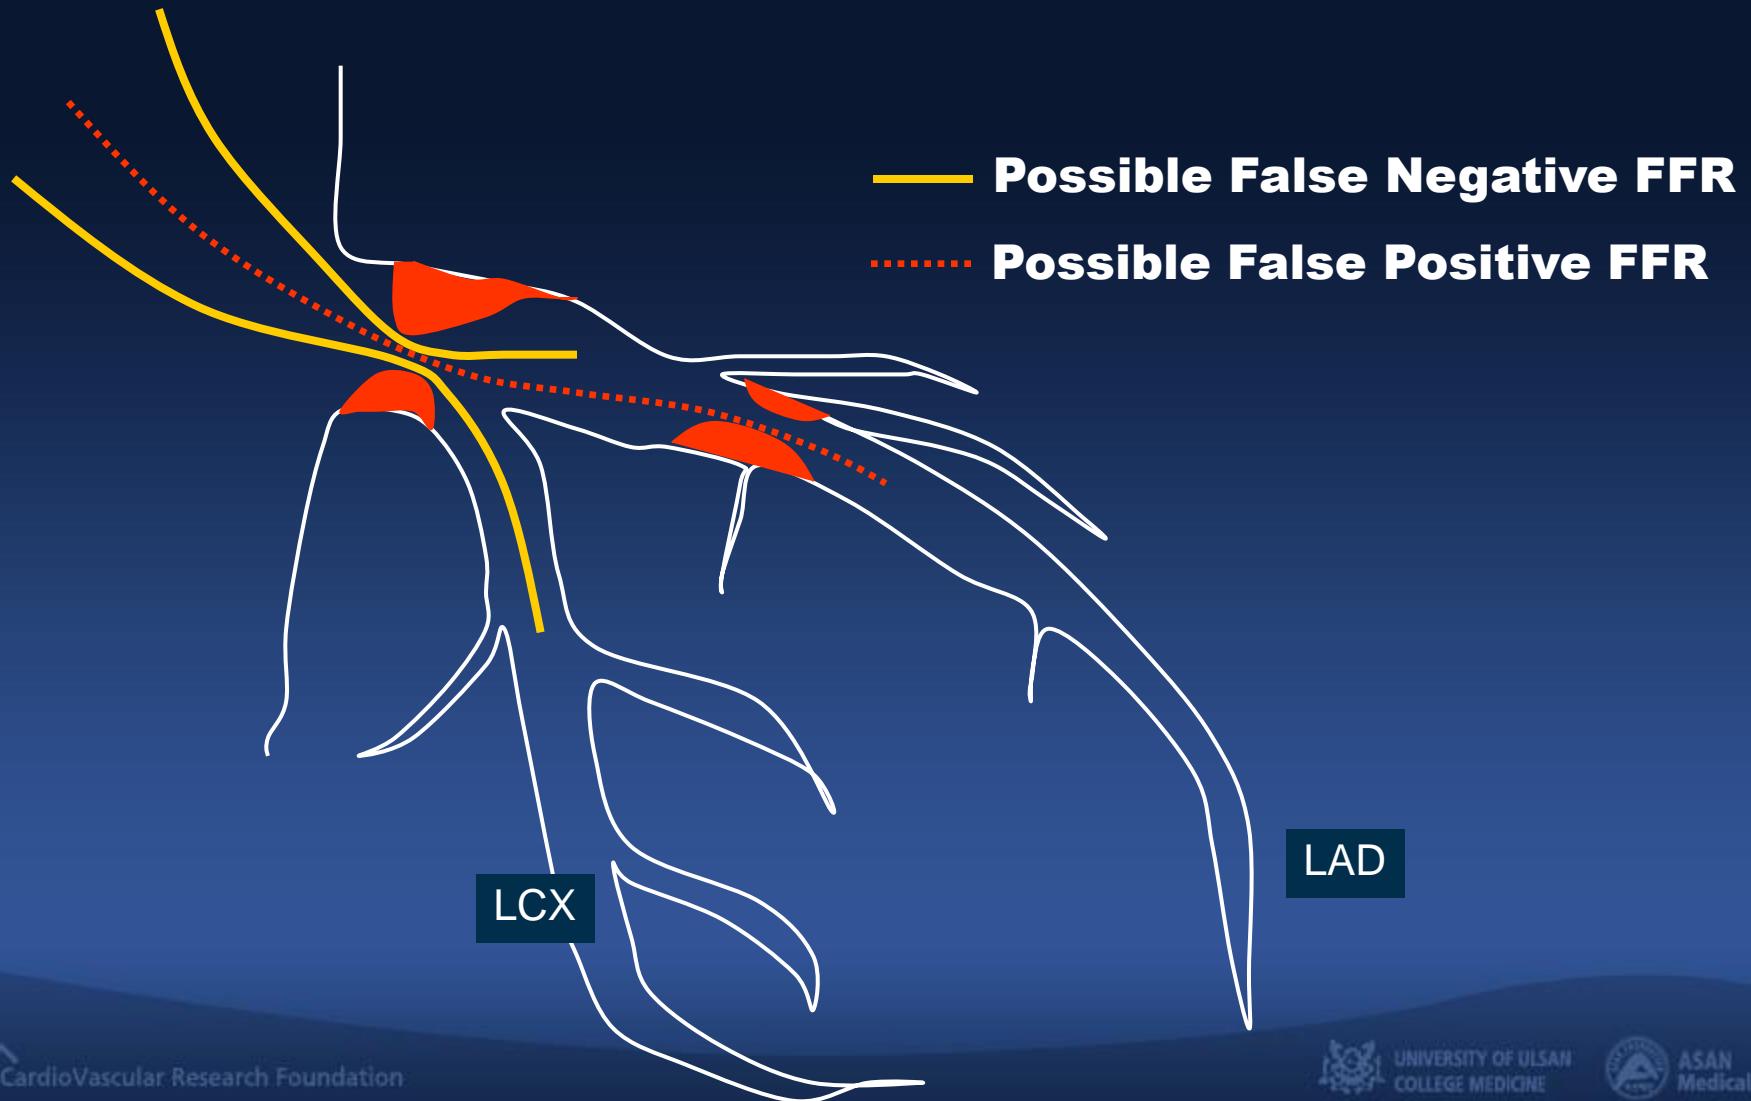

Single Stent Cross Over or 2 Stents Technique.

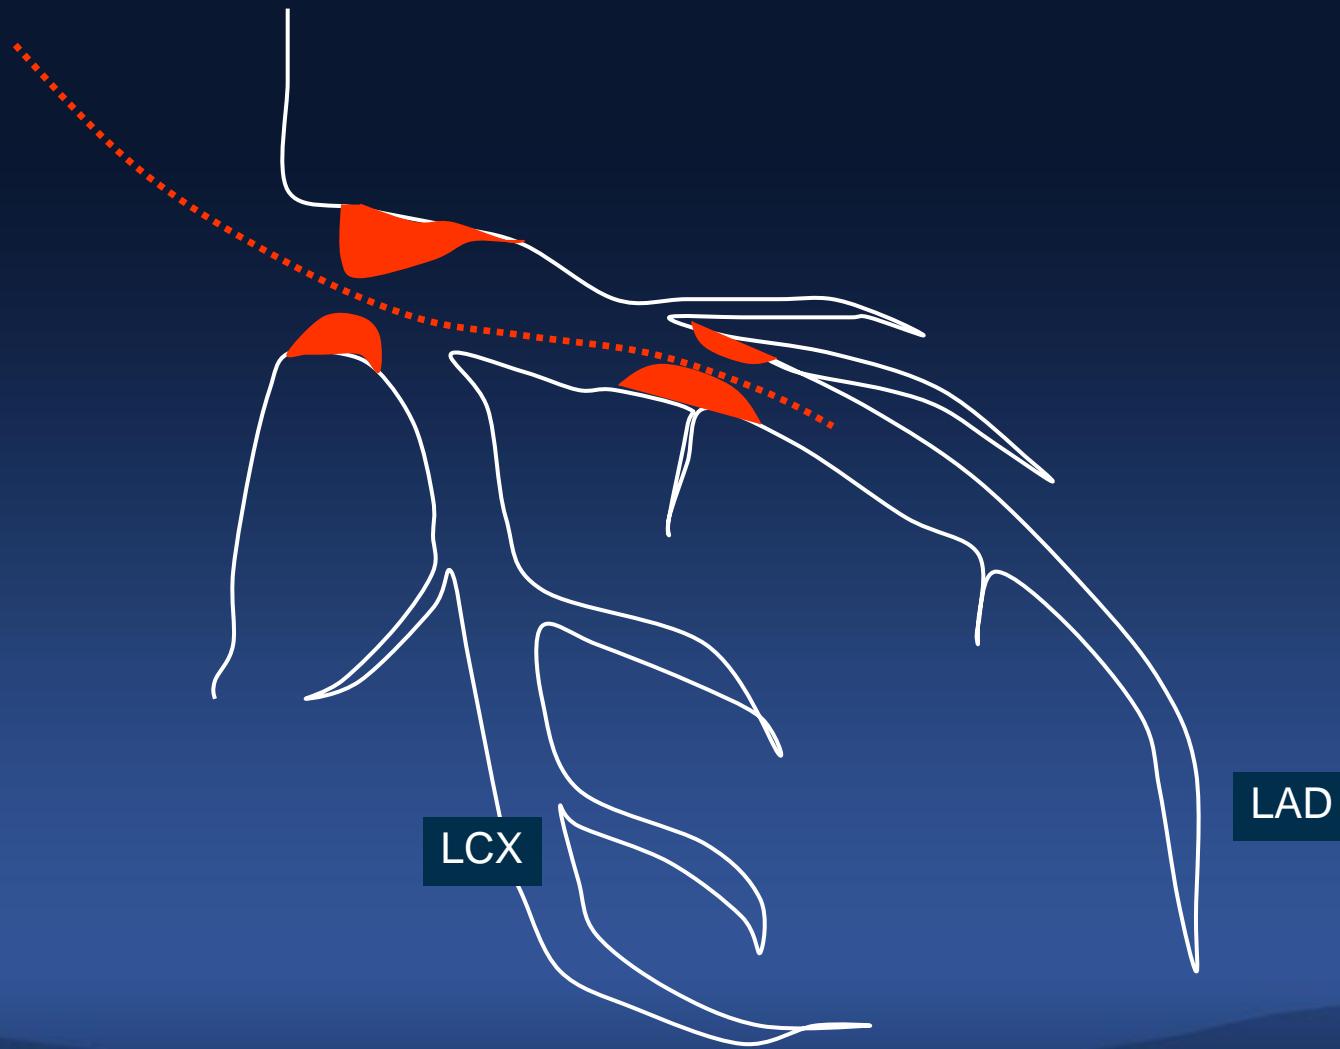

Practically, We Can Not Separately Treat

For LMCA stenosis with distal LAD/LCX stenosis

Tandem Lesions with Interposing side branch

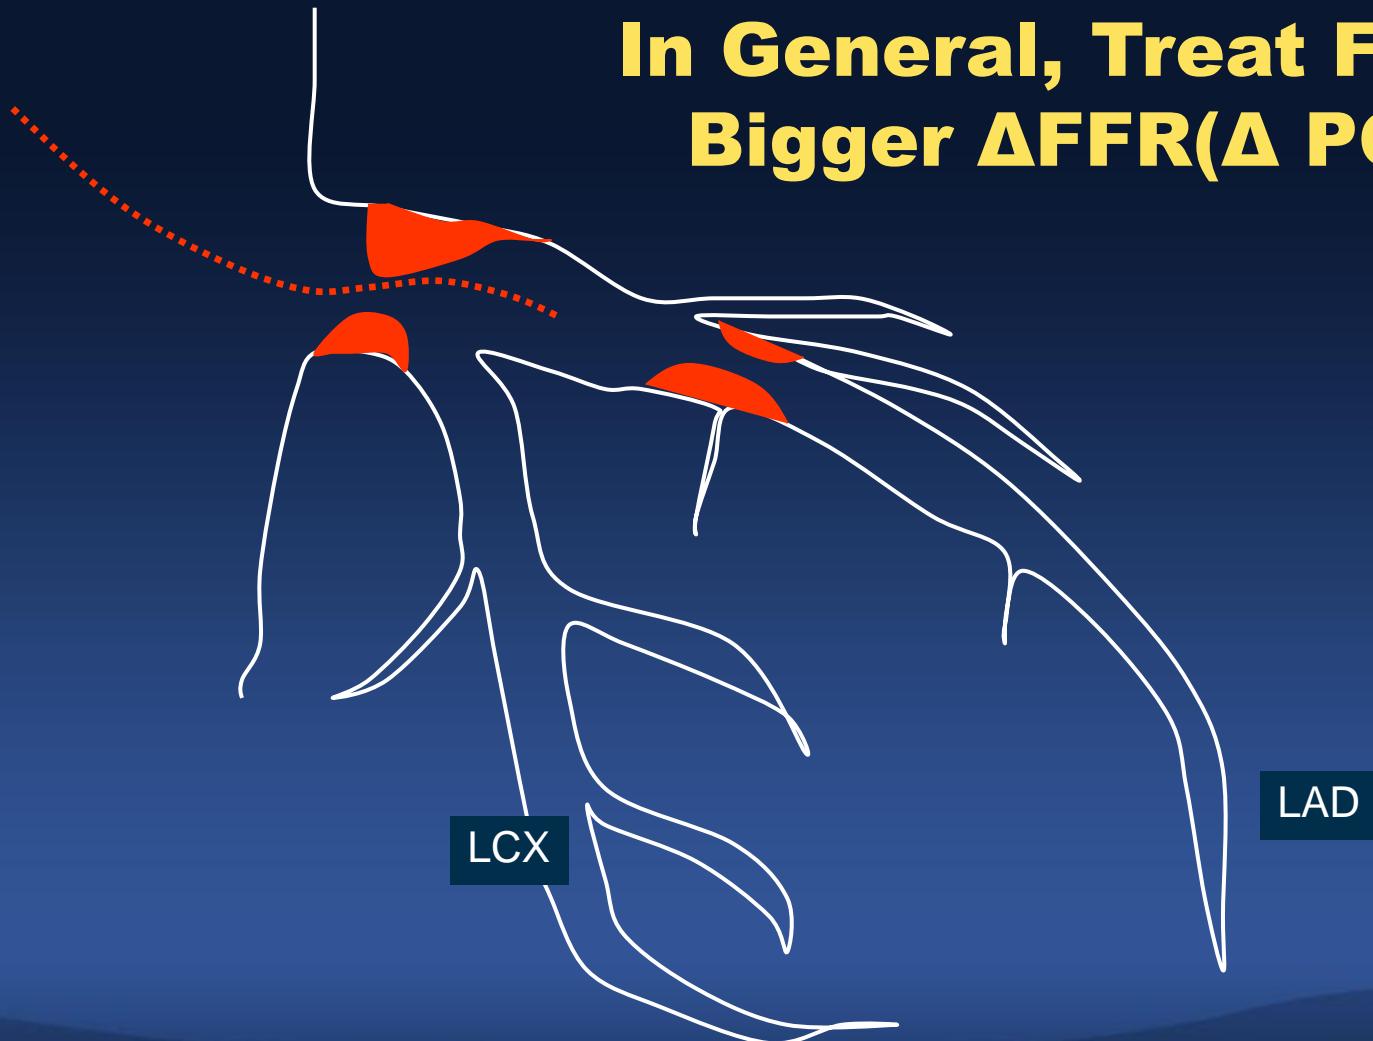

Pressure Wire Pull-Back Help To Decide the Treatment Sequence

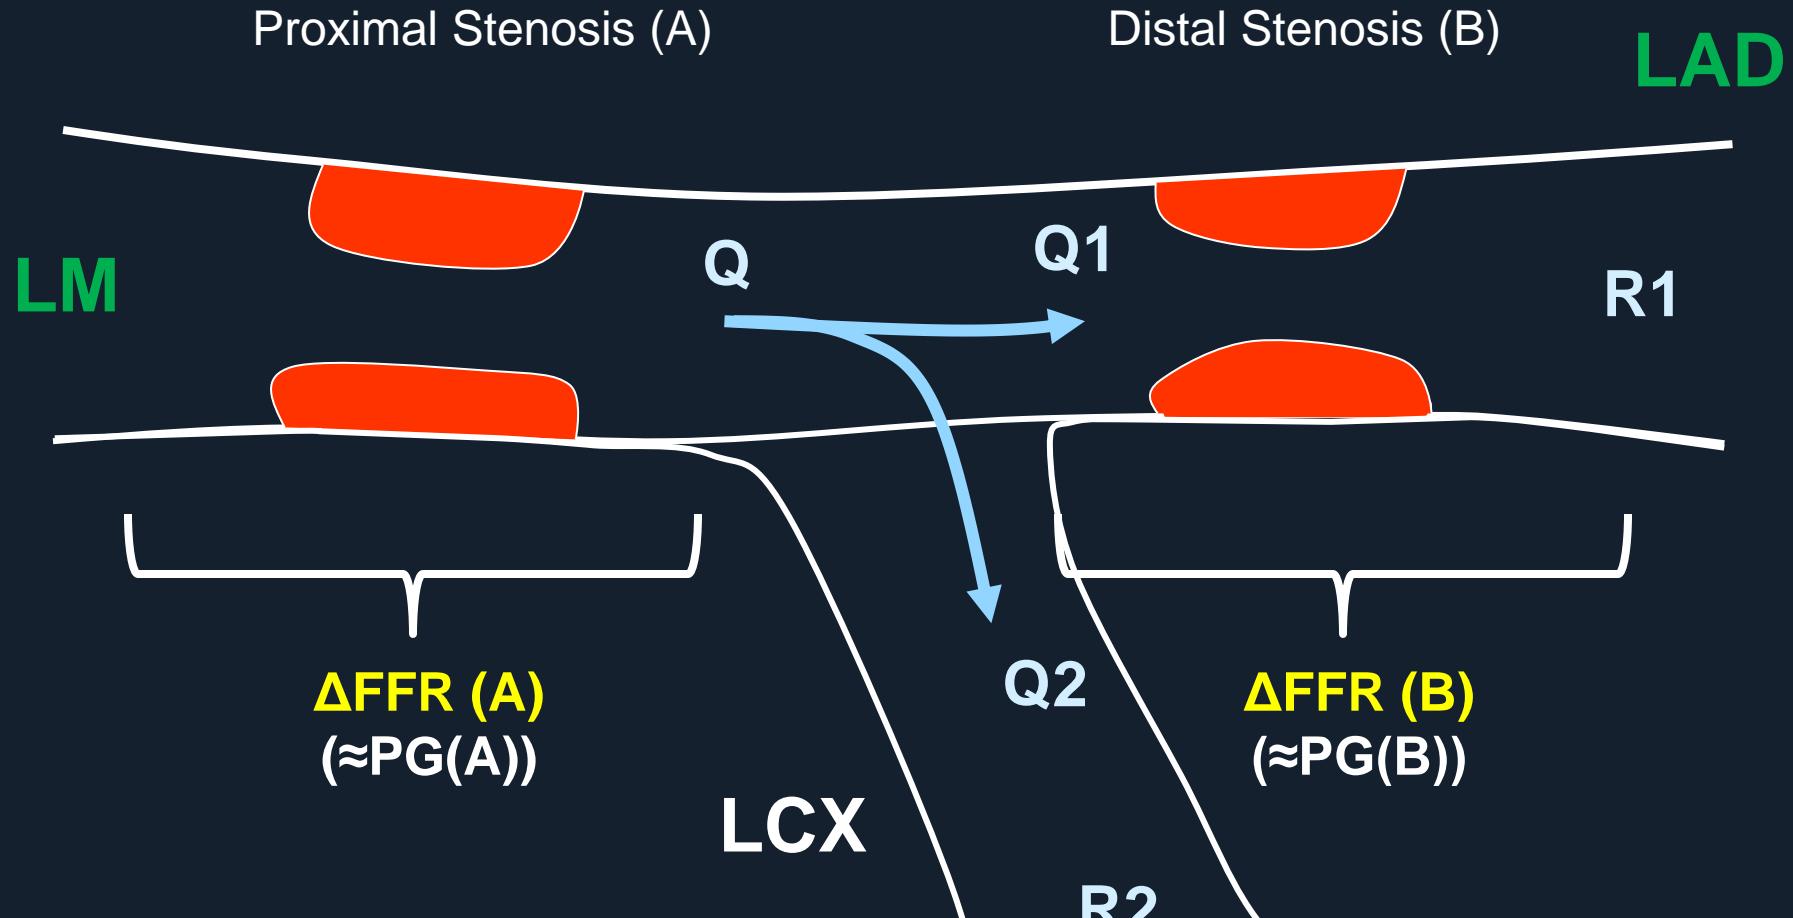

Pressure Wire Pull-Back Help To Decide the Treatment Sequence

In General, Treat First
Bigger Δ FFR(Δ PG)

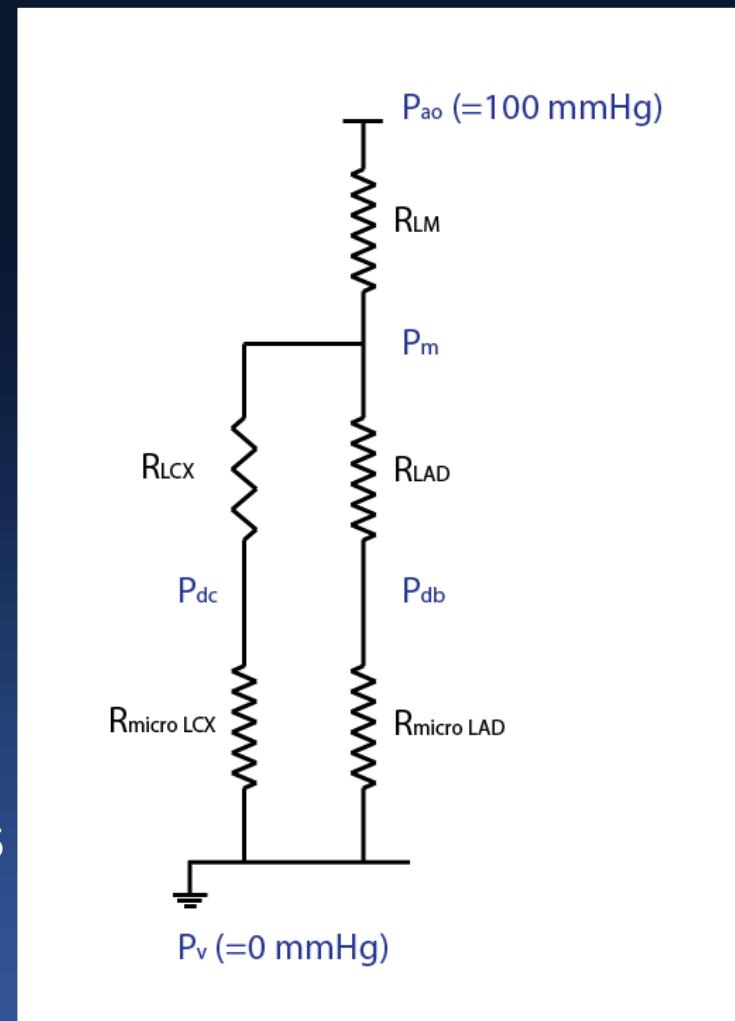

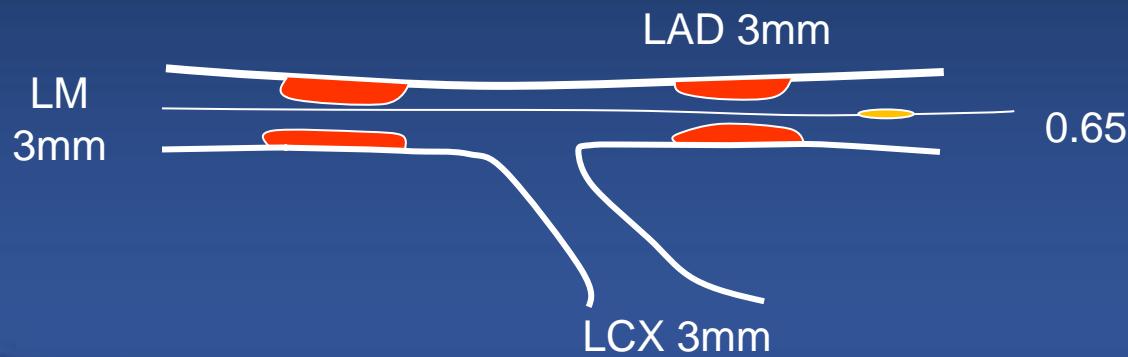

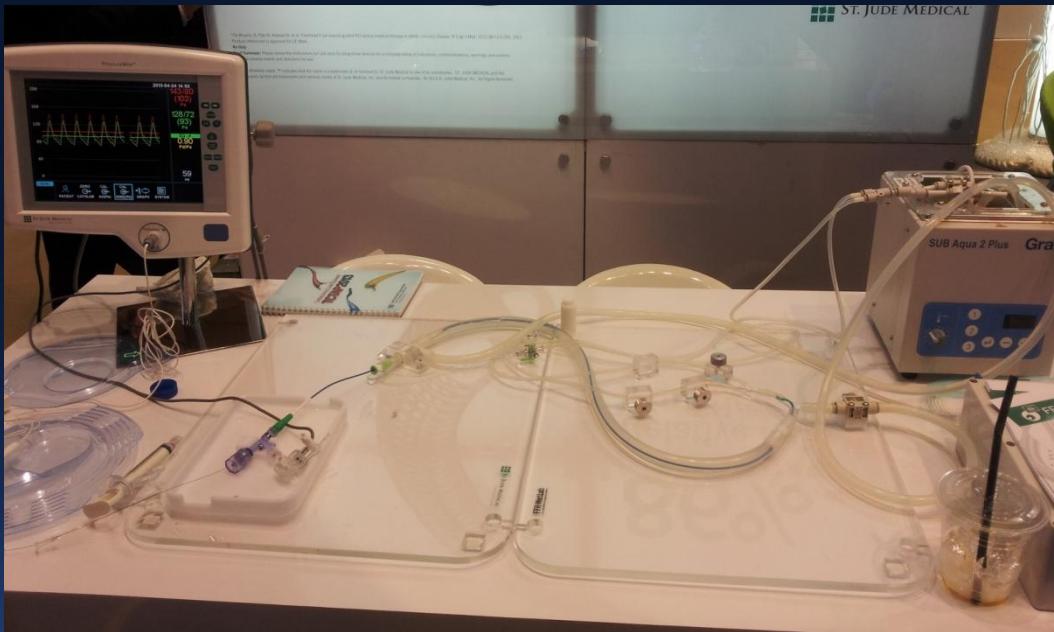

Tandem Lesion

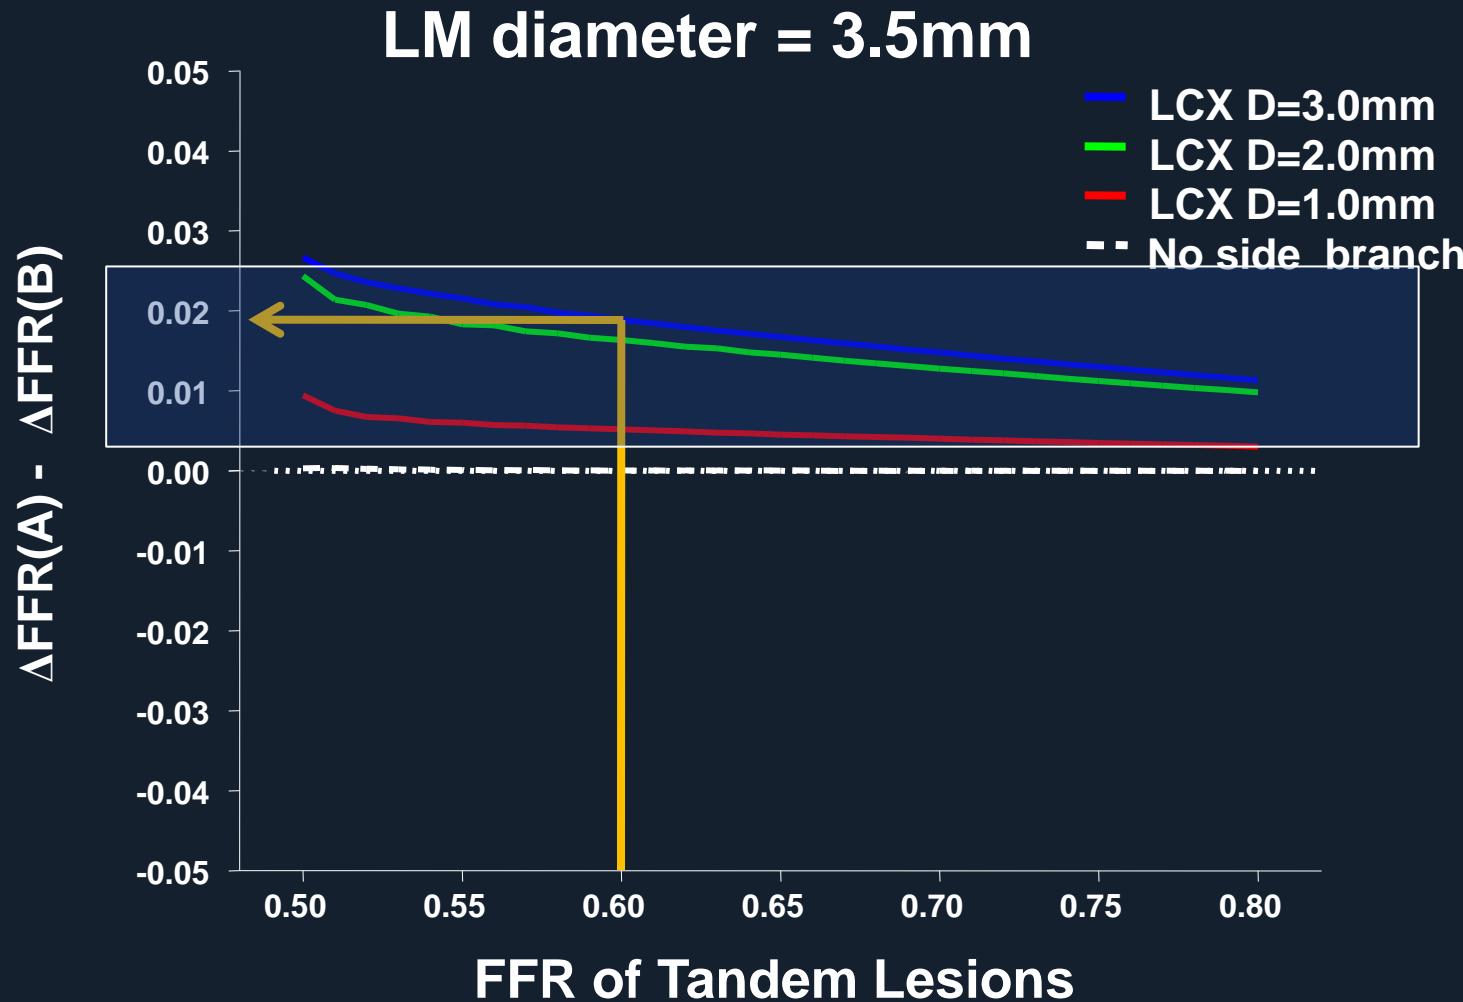

Could ΔFFR ($\approx \Delta PG$) be a Surrogate of Relative Functional Significance ?

In Vitro Simulation

When Two Lesions Are Functionally Equal,

$$(FFR(A)_{\text{true}} = FFR(B)_{\text{true}})$$

Pressure Wire Pull-Back Help To Decide the Treatment Sequence

In General, Treat First
Bigger Δ FFR(Δ PG)

The impact of side branch (≈ 0.02) should be considered,
But this number may be below the clinical significance.

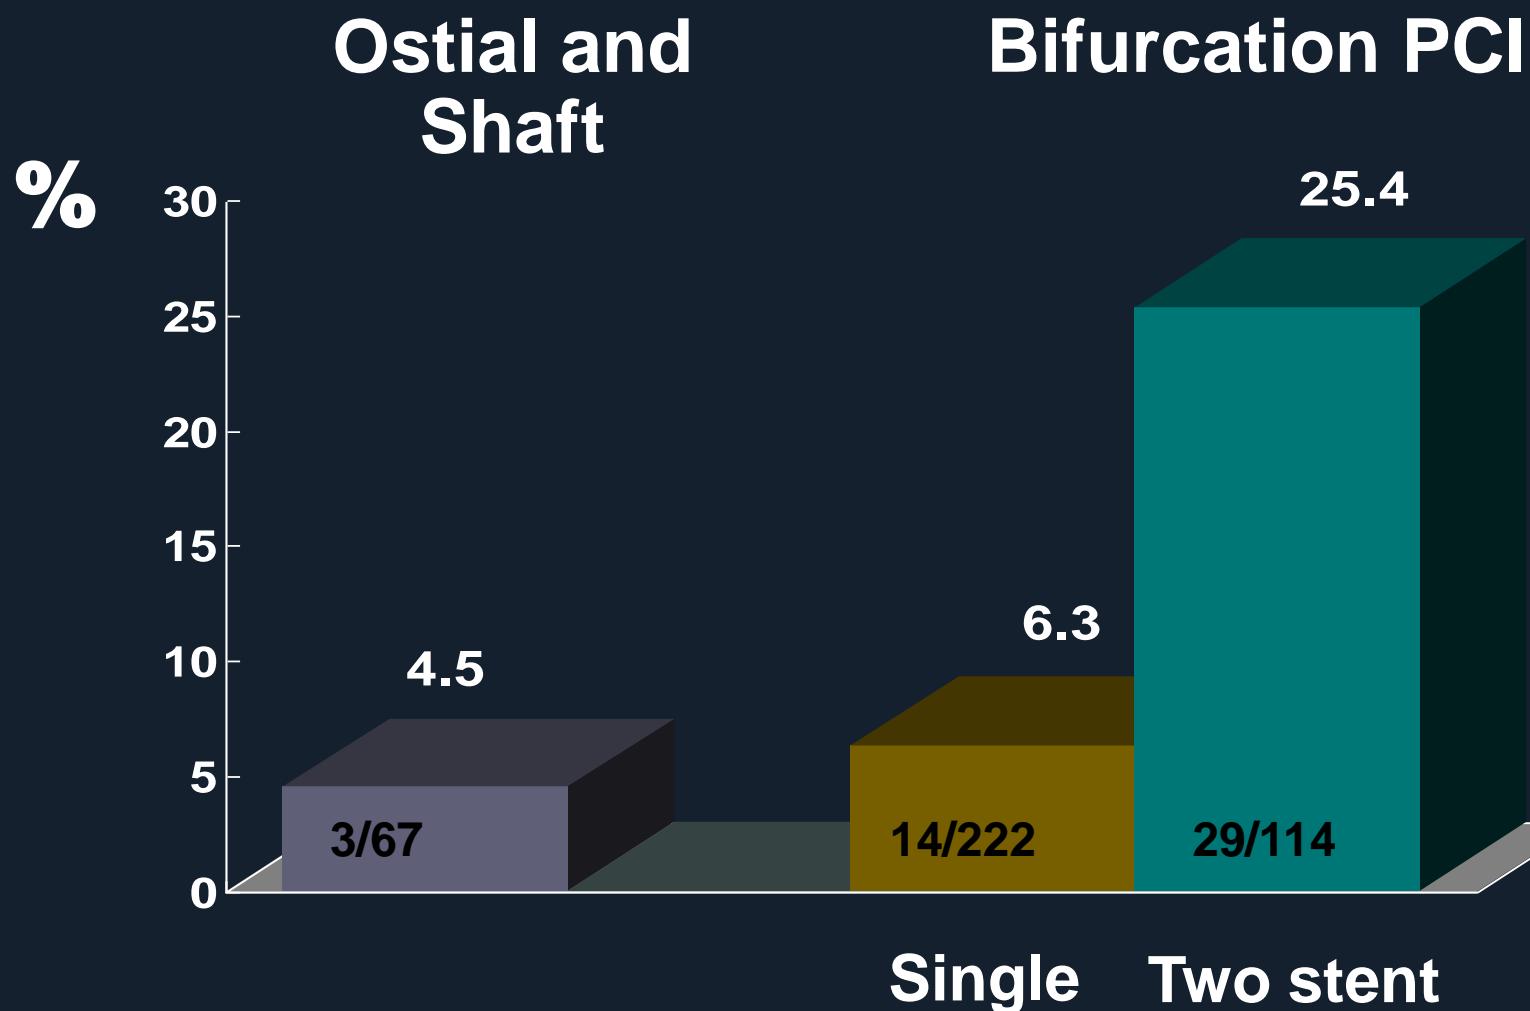

Why We Need IVUS in LM Stenting?

- Selection of Treatment strategies: 1 stent or 2 stents
- Post-Stent Optimization (5,6,7,8) Reduced ISR
- IVUS guided PCI in LMCA Improved the Survival
- Assist the Functional evaluation of Complex LM disease

Specificity	80%
PPV	83%
NPV	76%
Accuracy	80%

Park SJ et al. JACC-CI (In Press)

Integrated Use of FFR and IVUS in LM stenting

Ostial or Shaft Stenosis

Whether to Treat or Not: FFR guidance

How to Treat: IVUS guidance

- Preintervention IVUS evaluation
MLA, RVD, LL, Plaque burden etc.
- Postintervention IVUS optimization
 $MSA > 8\text{mm}^2$

Bifurcation Stenosis

Whether to Treat or Not: FFR guidance

- FFR measurement is important
Consider a bifurcation stenosis
as a single unit of disease
- IVUS can assist the functional
evaluation of complex LM disease
 $MLA < 4.5\text{mm}^2$

How to Treat: IVUS guidance

- Preintervention IVUS evaluation
MLA, RVD, LL, Plaque burden etc.
- Postintervention IVUS optimization
Evaluate MSA in every segment (5,6,7,8)
