Q1. Could OCT provide better information  
for detecting vulnerable plaque  
than other modalities?

# Pathologic Criteria for Vulnerable Plaque

Based on previously presented autopsy study

The vulnerable plaque characterized by thin fibrous cap, extensive macrophage infiltration, and large lipid core.

## Major criteria

Echolucent plaque  
Attenuated plaque

- Thin cap
- Endothelial dysfunction
- Fissured plaque
- Stenosis 90%

Ruptured plaque c/s thrombus

## Minor criteria

- Superficial calcified nodule
- Glistening yellow
- Intraplaque hemorrhage
- Endothelial dysfunction
- Cellular debris

Positive Remodeling

# Pathologic Criteria for Vulnerable Plaque

*Based on previously presented autopsy study*

## Major criteria

- Active inflammation (monocyte/macrophage and T-cell infiltration)
- Thin cap with large lipid core
- Endothelial denudation with superficial platelet aggregation
- Fissured plaque
- Stenosis 90%

## Minor criteria

- Superficial calcified nodule
- Glistening yellow
- Intraplaque hemorrhage
- Endothelial dysfunction
- Outward (positive) remodeling

OCT has a potential benefit to identify vulnerable plaques and also provides superficial information of the vessel during and after PCI.

OCT image moves closer to becoming a powerful diagnostic tool that will provide new insights into the etiology and clinical course of coronary artery disease.

### *The Major and Minor Criteria for Vulnerable Plaque*

- 48 Patients (48 lesions) were enrolled and categorized according to their clinical presentation into SAP (n=15) and ACS (n=33).
