# Can IVUS and FFR be helpful to treat ISR lesions ?

Pure  
intima hyperplasia

High  
risk plaque

# Introduction

Although drug-eluting stent improved the late outcome as compared with Bare metal stent, in-stent restenosis (ISR) is still major limitation of coronary intervention.

The newly "created" stenosis within the stented lumen need to be defined to treat whether revascularization is not necessary, and medical treatment can be used instead.

It has been suggested that the application of fractional flow reserve (FFR) measurements may helpful in angiographically moderate ISR lesions

*(López-Palop et al, Eur Heart J. 2004;25:1970-1971)*

*(Krüger et al, Chest. 2005;128:1645-1649)*

FFR was not valid to predict optimal stent expansion according to IVUS criteria but could delineate under-expanded stents despite a reasonable angiographic appearance.

*(Stempfle et al, Int J Cardiovasc Intervent. 2005;7:101-107)*

Pathologic studies have been suggested that the technology of DES now accelerated atherosclerosis and potentially greater late thrombosis.

Atherosclerotic change was seen in 10% of BMS lesions (8 of 77) vs in DES lesions (35%; 23 of 66;  $p=0.0004$ ).

Earliest necrotic core 9 months of DES vs 5 years in BMS.

*(Hasegawa et al. CCI 2006;68:554–8) (Nakazawa et al. JACC Img 2009;2:625-8)*

## *Case 1. In-Stent Restenosis; Fibrofatty*

F/67, Unstable angina

Chief complaint: chest pain recurred

Pico Elite stent 3.5x16 mm, pLAD

TC 116 mg/dl, LDL 76 mg/dl, HDL 32 mg/dl, TG 163 mg/dl

Pitavastatin 2 mg/day

Follow-up CAG after 4 months

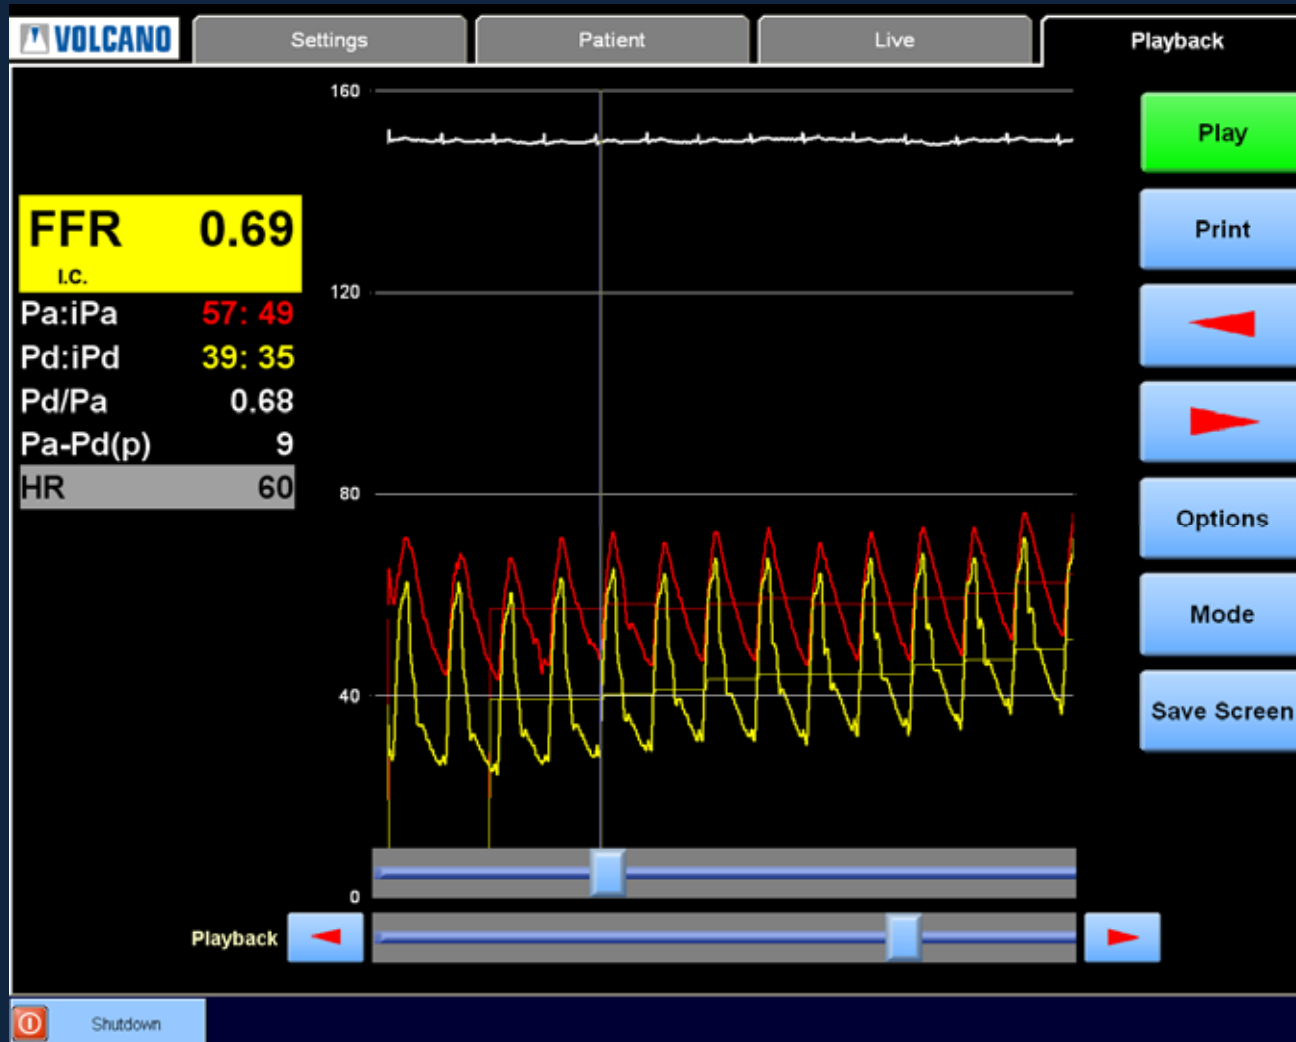

EEM area (mm <sup>2</sup> )	17.5
Lumen area (mm <sup>2</sup> )	1.9
Stent area (mm <sup>2</sup> )	9.7
Minimal stent area (mm <sup>2</sup> )	8.0
IH area (mm <sup>2</sup> )	7.8
Plaque area (mm <sup>2</sup> )	7.8
Plaque burden( %)	89.3
Remodeling index	1.04

Fibrotic area (mm <sup>2</sup> )	3.8
Fibrofatty area (mm <sup>2</sup> )	1.3
Necrotic area (mm <sup>2</sup> )	0.2
Dense calcium area (mm <sup>2</sup> )	0
Fibrotic area (%)	71
Fibrofatty area (%)	24
Necrotic area ( %)	4.6
Dense calcium area (%)	0.6

maximum IH necrotic core site

# Intracoronary Adenosine Injection 60 ug

## *Case 2. In-Stent Restenosis; Necrotic*

M/58, Unstable angina

Routine follow-up , no chest pain

Two Taxus stent ; 3.0x16 mm, pLAD

3.0x12 mm, 1<sup>st</sup> diagonal

Final Kissing balloon technique

TC 219 mg/dl, LDL 111 mg/dl, HDL 54 mg/dl, TG 315 mg/dl

Pitavastatin 2 mg/day

Follow-up CAG after 9 months

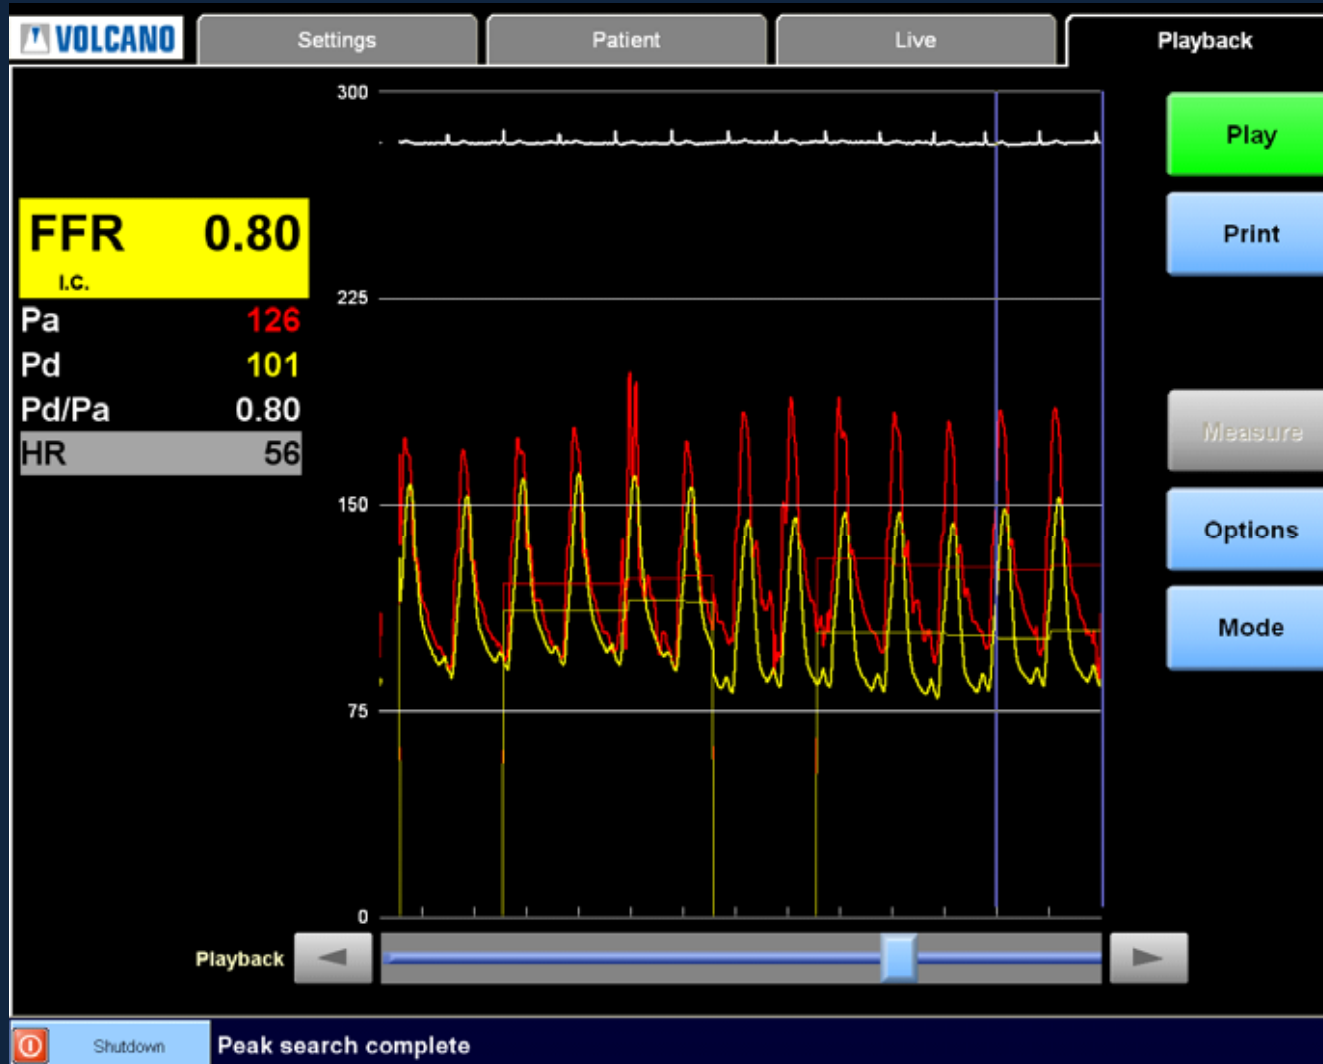

EEM area (mm <sup>2</sup> )	13.1
Lumen area (mm <sup>2</sup> )	3.1
Stent area (mm <sup>2</sup> )	8.2
Minimal stent area (mm <sup>2</sup> )	6.6
IH area (mm <sup>2</sup> )	5.1
Plaque area (mm <sup>2</sup> )	14
Plaque burden( %)	89.3
Remodeling index	1.16

Fibrotic area (mm <sup>2</sup> )	3.1
Fibrofatty area (mm <sup>2</sup> )	0.2
Necrotic area (mm <sup>2</sup> )	1.3
Dense calcium area (mm <sup>2</sup> )	0.1
Fibrotic area (%)	66
Fibrofatty area (%)	5.2
Necrotic area ( %)	27.7
Dense calcium area (%)	1.1

maximum IH necrotic core site

# Intracoronary Adenosine injection 60 ug

# Discussion

Nakazawa et al. J Am Coll Cardiol Img 2009;2:625-8

Can IVUS and FFR be helpful to treat In-Stent Restenosis lesions ? Yes, Of Course.

1) How to assess the newly "created" prominent necrotic core within the stented lumen ?

Which treatment strategy will be appropriate to treat ? - Statin vs PCI

2) Although FFR looks reasonable, however the cut-off value 0.75 is enough for the newly "created" prominent necrotic core ?

*Thank you for your attention*
