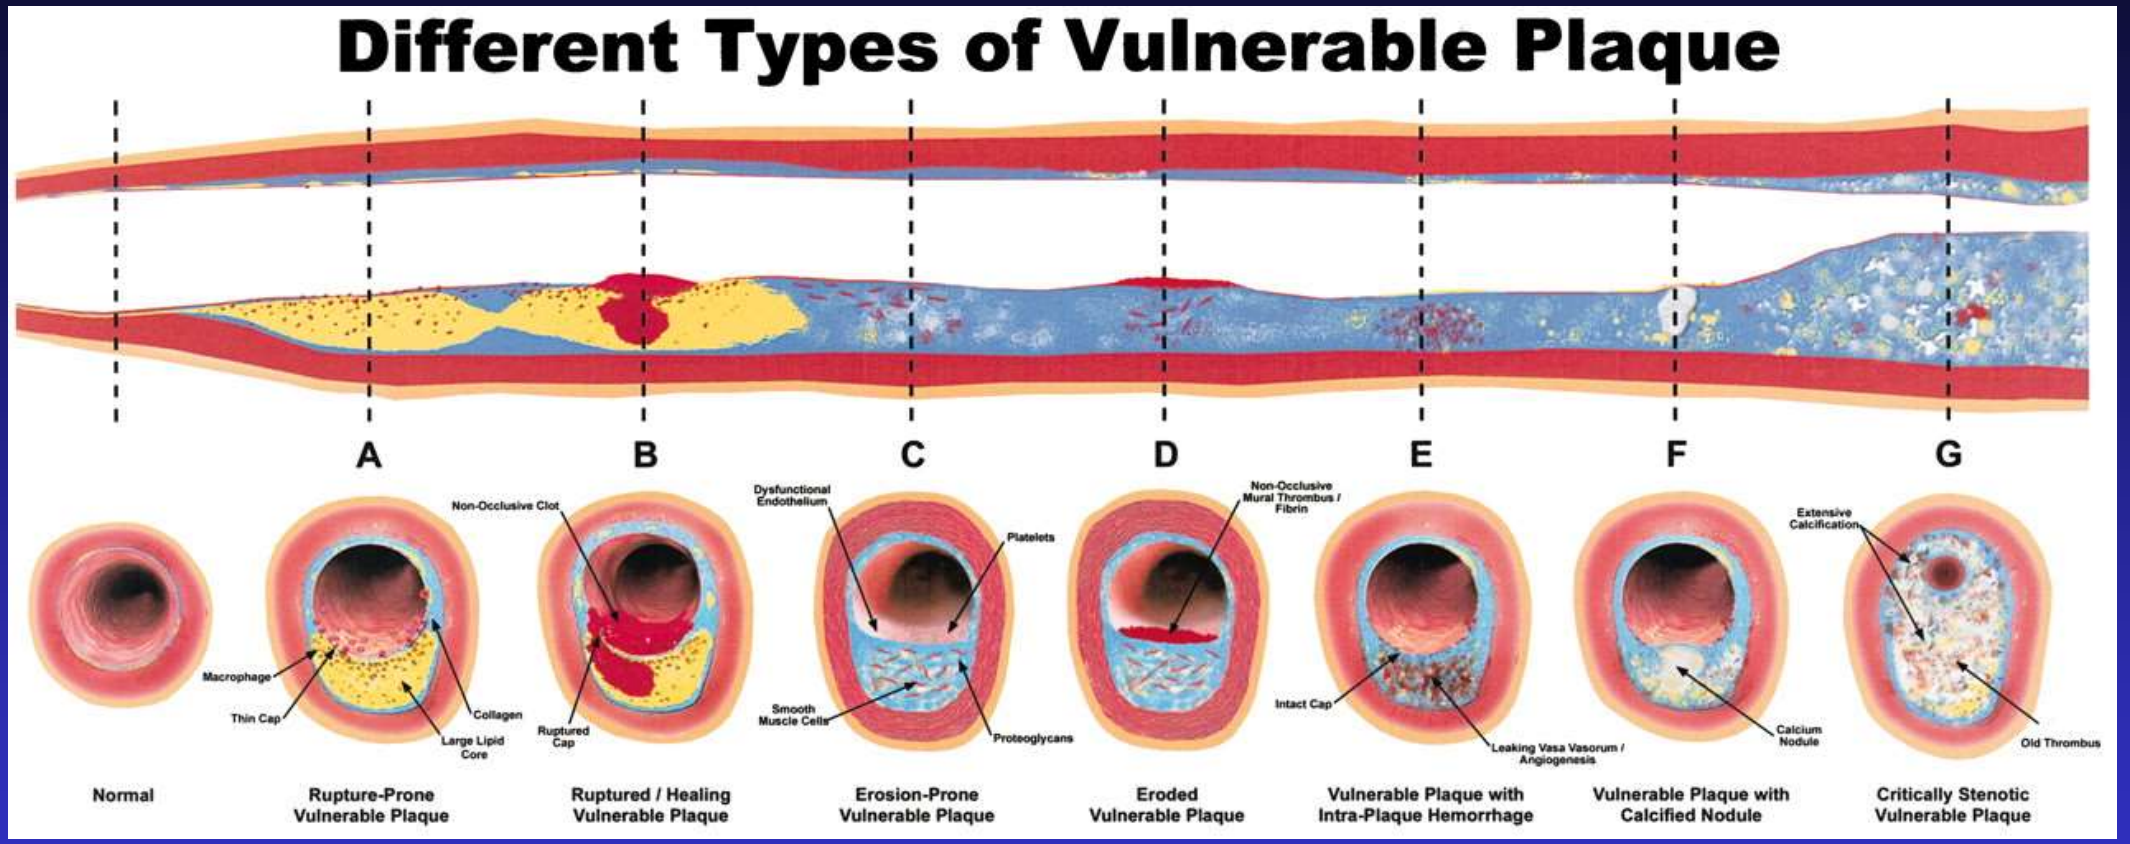
Progression of atherosclerotic plaque

(Naghavi M, et al. Circulation 2003;108:1664-1672)



Positive remodeling can be identified in the early stage and this is thought to be an initial adaption for atherosclerotic change. Finally, vessel become narrowing significantly according to atheroscrelosis. ACS may occur even in insignificant stenosis.

Silent plaque rupture
Optical coherence tomography
Non-ST elevation acute coronary syndrome

ABSTRACT

Background: Autopsy studies have reported that rupture of a thin-cap fibroatheroma and subsequent thrombus formation is the major mechanism leading to acute coronary syndrome (ACS). However, it is not clear why only some plaque ruptures lead to ACS. Optical coherence tomography (OCT) is a high-resolution imaging modality which is capable of investigating detailed coronary plaque morphology in vivo. The objective of this study was to determine whether ruptured plaque morphology assessed by OCT differs between asymptomatic coronary artery disease (CAD) and non-ST elevation acute coronary syndrome (NSTEACS).

Methods: We examined ruptured plaque morphology using OCT in 80 patients, 33 with asymptomatic CAD and 47 with NSTEACS.

Results: The frequency of lipid-rich plaque and intracoronary thrombus was significantly lower in asymptomatic CAD than in NSTEACS (61% vs. 85%, $p = 0.013$ and 9% vs. 83%, $p < 0.001$, respectively). Although maximal ruptured cavity cross-sectional area (CSA) was similar in both groups, lumen area at the rupture site and minimal lumen area were significantly larger in asymptomatic CAD than in NSTEACS (3.78 ± 1.50 mm^2 vs. 2.70 ± 1.55 mm^2, $p = 0.003$ and 2.75 ± 0.99 mm^2 vs. 1.72 ± 0.90 mm^2, $p < 0.001$, respectively).

Conclusions: OCT revealed that the morphology of ruptured plaques differs between asymptomatic CAD and NSTEACS in terms of lumen area and the frequency of lipid-rich plaques and thrombi. These morphological features may be associated with the clinical presentation of CAD.

Table 3

OCT findings of target lesions.

	Asymptomatic CAD ($n = 33$)	NSTEACS ($n = 47$)	p-Value
Lipid-rich plaque, n (%)	22 (67)	40 (85)	0.013
Lipid arc, degree	133 ± 71	169 ± 71	0.031
Thrombus, n (%)	3 (9)	39 (83)	<0.001
Red thrombus, n (%)	0 (0)	15 (32)	<0.001
White thrombus, n (%)	3 (9)	24 (51)	<0.001
Ruptured cap thickness, μm	69 ± 24	62 ± 22	0.165
Maximal ruptured cavity area, mm^2	1.63 ± 0.86	1.66 ± 1.35	0.884
Lumen area at rupture site, mm^2	3.78 ± 1.50	2.70 ± 1.55	0.003
MLA, mm^2	2.75 ± 0.99	1.72 ± 0.90	<0.001
Location of maximum ruptured cavity			0.380
Proximal to the MLA site, n (%)	9 (27)	10 (21)	
MLA site, n (%)	11 (33)	23 (49)	
Distal to the MLA site, n (%)	13 (40)	14 (30)	

Values are given as n (%) or mean ± standard deviation. CAD = coronary artery disease; MLA = minimal lumen area; NSTEACS = non-ST elevation acute coronary syndrome.

Table 4

OCT findings of target lesions after excluding patients with thrombus aspiration.

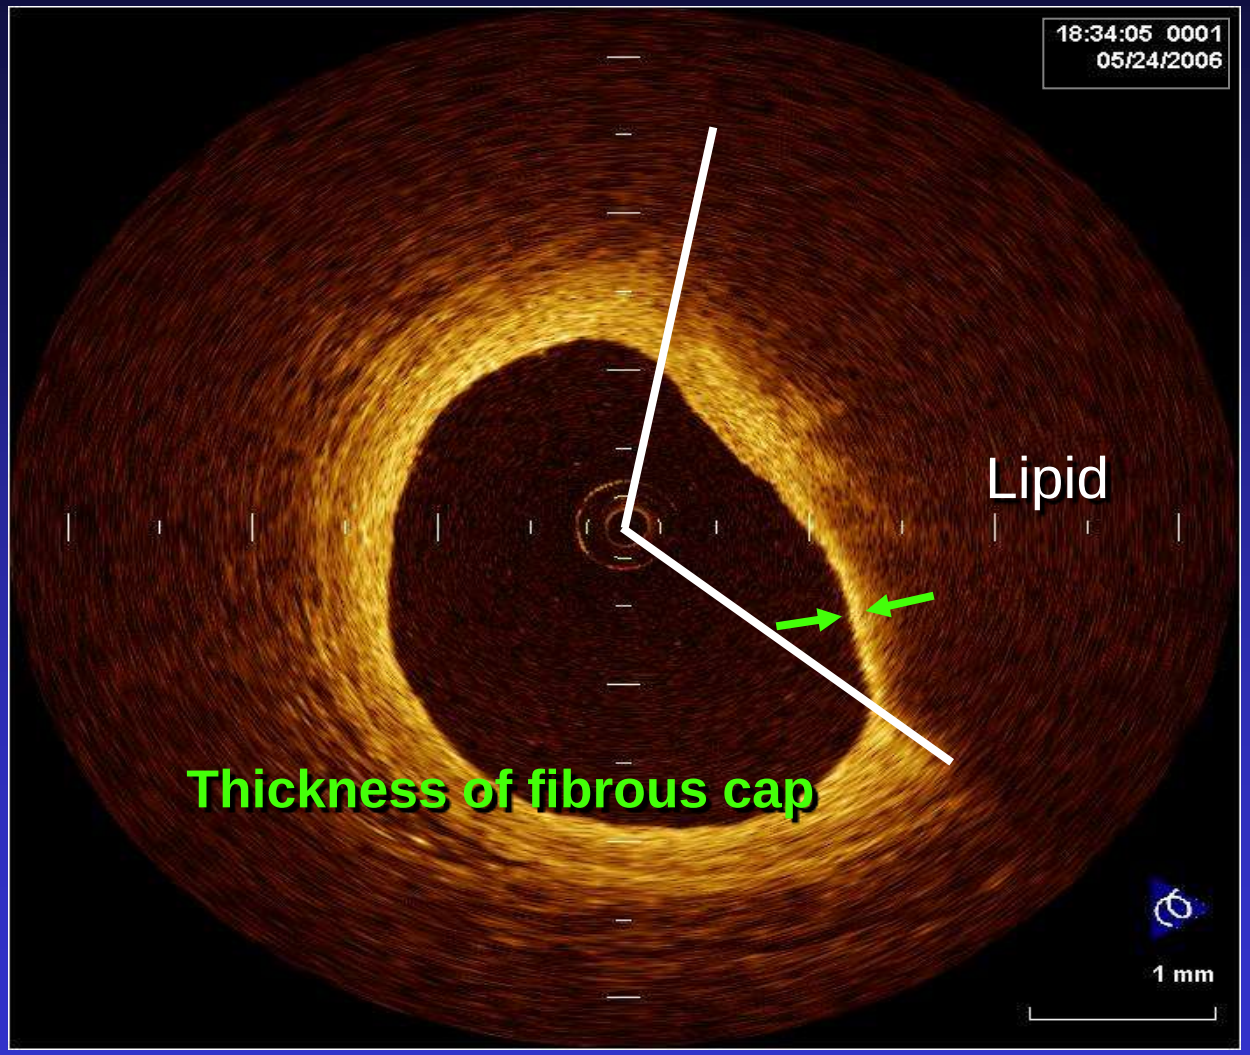
	Asymptomatic CAD ($n = 33$)	NSTEACS ($n = 32$)	p-Value
Lipid-rich plaque, n (%)	22 (67)	28 (88)	0.046
Lipid arc, degree	133 ± 71	171 ± 71	0.037
Thrombus, n (%)	3 (9)	25 (78)	<0.001
Red thrombus, n (%)	0 (0)	9 (28)	<0.001
White thrombus, n (%)	3 (9)	16 (50)	<0.001
Ruptured cap thickness, μm	69 ± 24	60 ± 23	0.142
Maximal ruptured cavity area, mm^2	1.63 ± 0.86	1.79 ± 1.43	0.573
Lumen area at rupture site, mm^2	3.78 ± 1.50	2.76 ± 1.58	0.009
MLA, mm^2	2.75 ± 0.99	1.79 ± 0.92	<0.001
Location of maximum ruptured cavity			0.538
Proximal to the MLA site, n (%)	9 (27)	7 (22)	
MLA site, n (%)	11 (33)	15 (47)	
Distal to the MLA site, n (%)	13 (40)	10 (31)	

Values are given as n (%) or mean ± standard deviation. CAD = coronary artery disease; MLA = minimal lumen area; NSTEACS = non-ST elevation acute coronary syndrome.

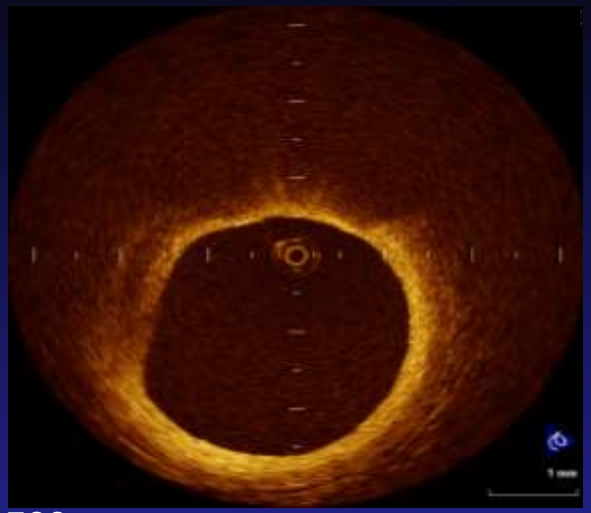
Thin-capped Fibroatheroma (TCFA)

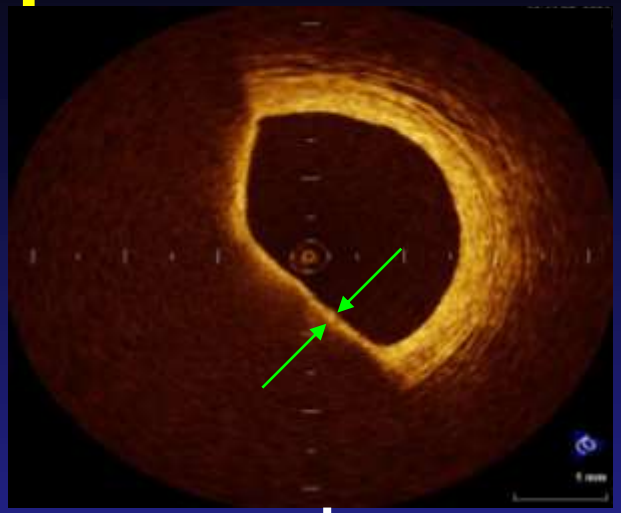
The TCFA was defined as a plaque with lipid content in more than 2 quadrants and the thinnest part of a fibrous cap measuring less than 65 μm by histology.

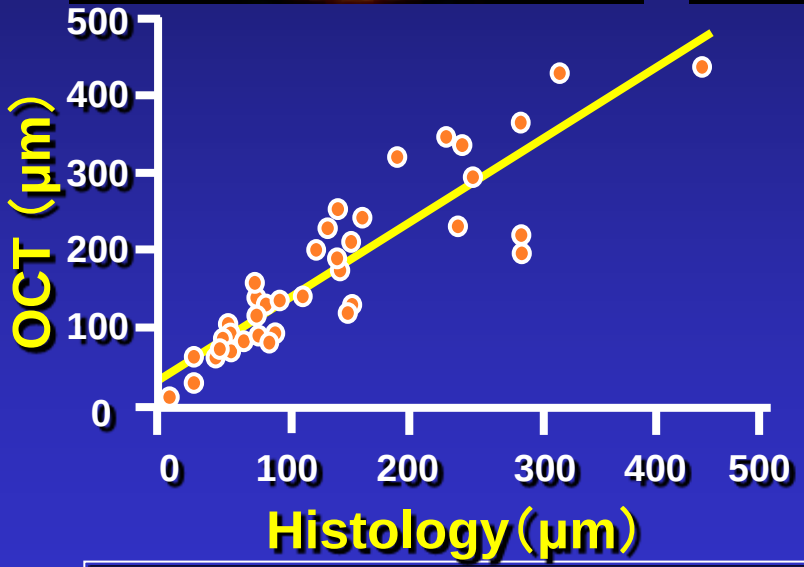
The cap thickness is measured from the surface of the lumen to the portion just starting the attenuation

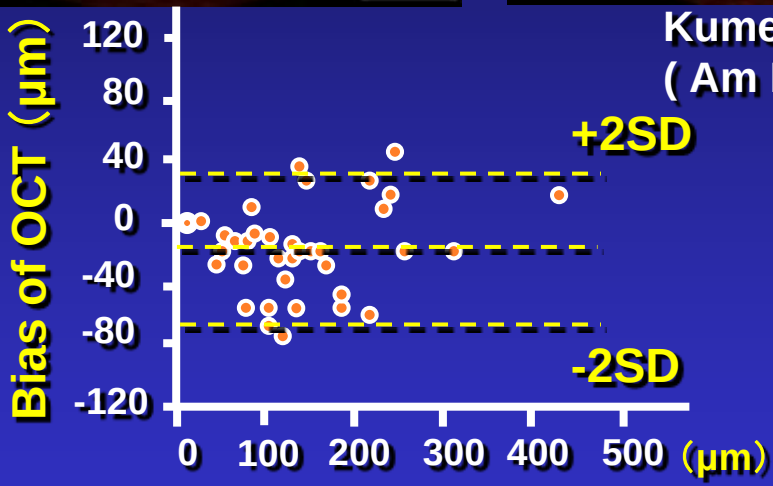


Thin-cap fibroatheroma (TCFA)









Kume T, Akasaka T, et al
(Am Heart J.152:755, 2006)

TCFA is demonstrated by the thin high intensity layer with rapid attenuation of the signals, and the cap thickness is measured by the thickness from the surface of the lumen to the portion just starting the attenuation.

Distribution of disrupted fibrous-cap thickness

Definition of TCFA in vitro defined by histology would be reconsidered, because the cap thickness should be <100-150 in vivo by OCT.

Criteria for defining vulnerable plaque

(Naghavi M, et al. Circulation 2003;108:1664-1672)

Major criteria

- **Active inflammation (monocyte/macrophage and sometimes T-cell infiltration)**
- **Thin cap (< 65 μm) with large lipid core**
- **Endotherial denudation with superficial platelet aggregation**
- **Fissued plaque**
- **Stenosis > 90%**

Minor criteria

- **Superficial calcified nodule**
- **Glistening yellow**
- **Intraplaque hemorrhage**
- **Endotherial dysfunction**
- **Outward (positive) remodering**

Criteria for defining vulnerable plaque

(Naghavi M, et al. Circulation 2003;108:1664-1672)

Major criteria

- Active inflammation
  (monocyte/macrophage and sometimes T-cell infiltration)
- Thin cap (< 65 μm) with large lipid core
- Endotherial denudation with superficial platelet aggregation
- Fissued plaque
- Stenosis > 90%

Minor criteria

- Superficial calcified nodule
- Glistening yellow
- Intraplaque hemorrhage
- Endotherial dysfunction
- Outward (positive) remodering

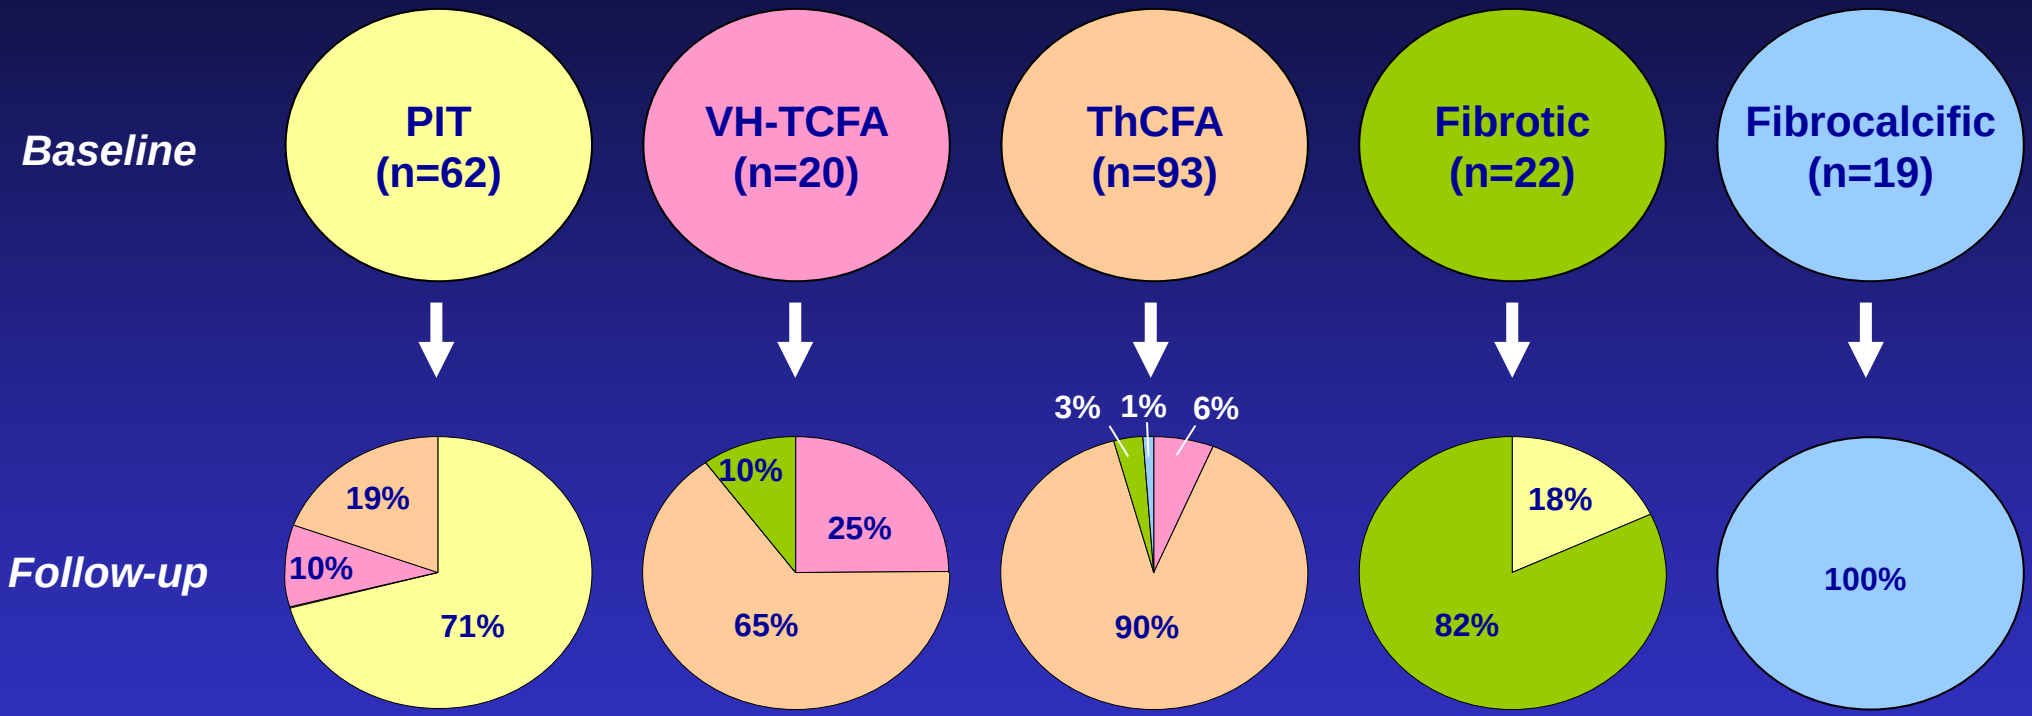
Changes in plaque characteristics



During follow-up, 75% of VH-TCFA evolved into a ThCFA or fibrotic plaque, and 25% remain unchanged. Conversely, 10% of PIT and 6% of ThCFA evolved into VH-TCFAs. No fibrotic plaque and fibrocalcific plaque evolved into fibroatheromas.

Summary (1)
Detection of VP & Natural Course by OCT

- Similar morphology can be demonstrated at the culprit lesions in ACS including plaque disruption, such as rupture, erosion & calcified nodule, thrombus, TCFA, lipid rich plaques, etc.
- Several differences could be identified at the culprit sites among different types of ACS and silent plaque disruption showing types of disruption and thrombus, size of MLA and ruptured cavity, position of disruption, etc.
- Although TCFA is thought to be a precursor of plaque disruption, further prospective study would be requested to predict future MACE as a vulnerable plaque (VP) relating to future events.
- OCT may be the most useful modality to demonstrate VP, further prospective study would be required to confirm its ability in the assessment of VP.

Summary (2)

Detection of VP & Natural Course by OCT

- Although development of various imaging modalities may allow us to demonstrate vulnerable plaques in some degree, prediction of future ACS might be difficult at the moment.
- According to the natural course of plaque morphology, it would be better to treat patients with coronary artery disease by stabilizing plaque vulnerabilities for ever.
- There are still possibilities of plaque sealing by intervention if the event rate of the interventions would be lower than MACE rate of VP.
