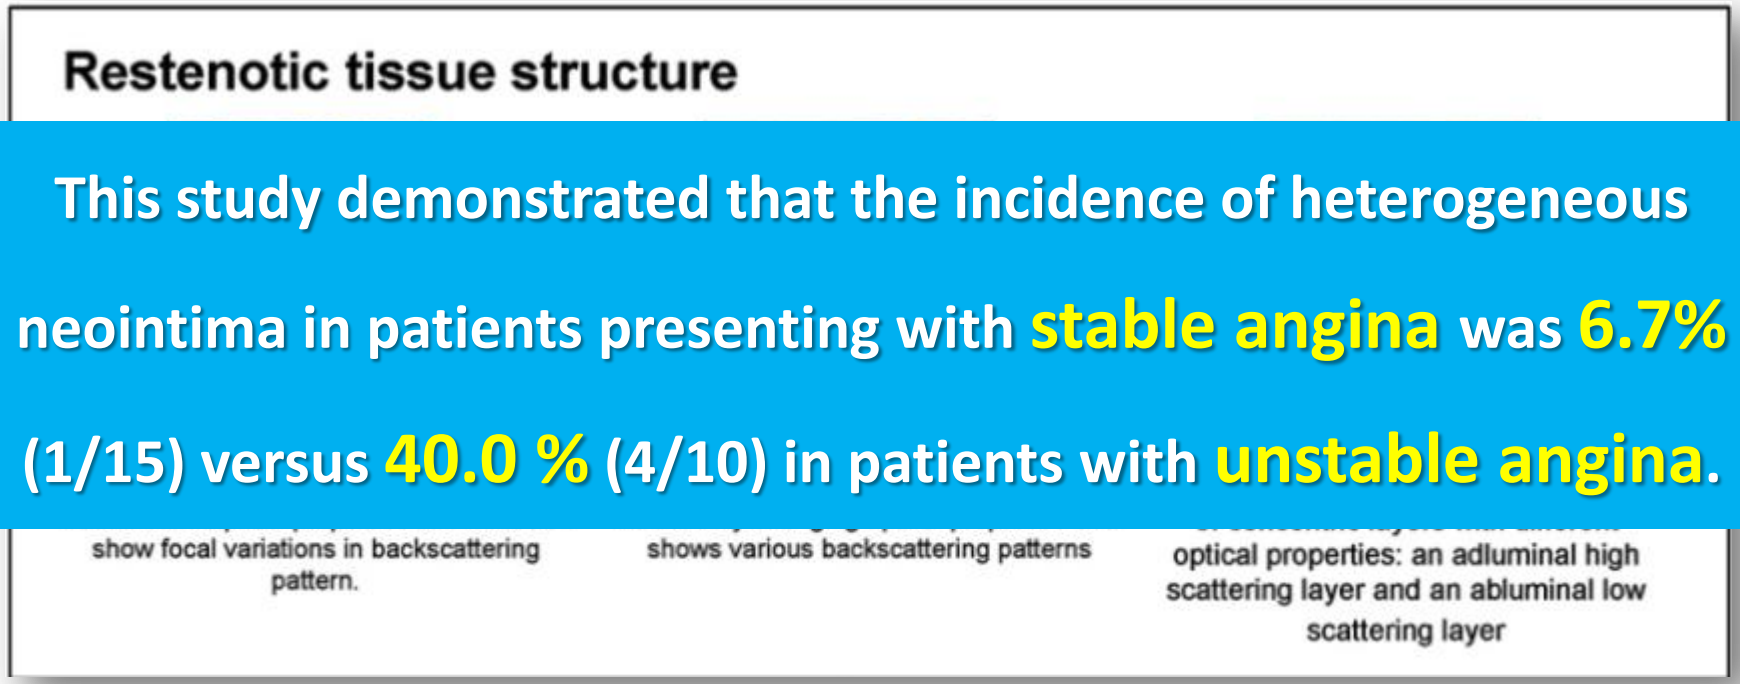
Neointimal tissue of In-stent Restenosis



This study demonstrated that the incidence of heterogeneous neointima in patients presenting with stable angina was 6.7% (1/15) versus 40.0 % (4/10) in patients with unstable angina.

	Angiographic classification			
	Diffuse (n = 9)	Focal (n = 11)	Margin (n = 5)	p
Layered	7 (77.8%)	5 (45.5%)	1 (20%)	0.005
Homogeneous	2 (22.2%)	1 (9.1%)	4 (80%)	
Heterogeneous	0	5 (45.5%)	0

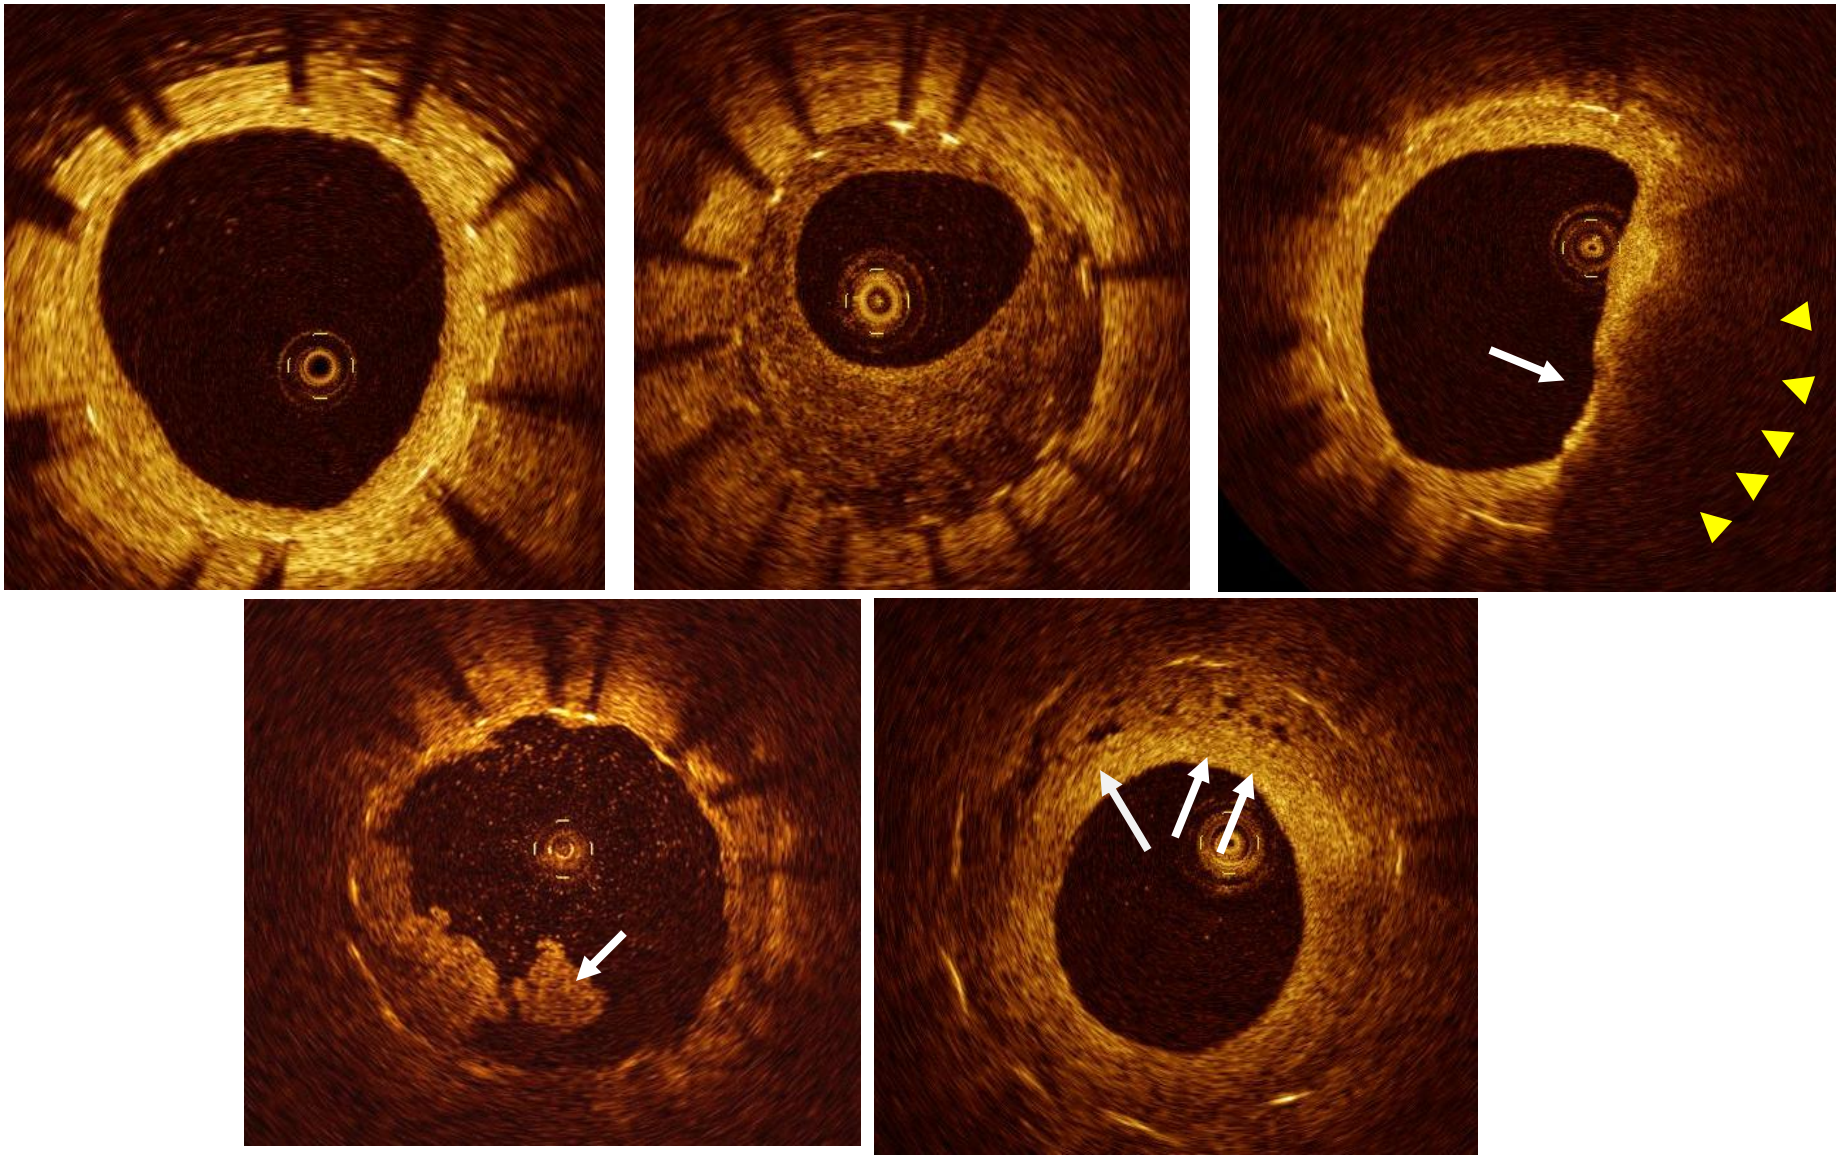
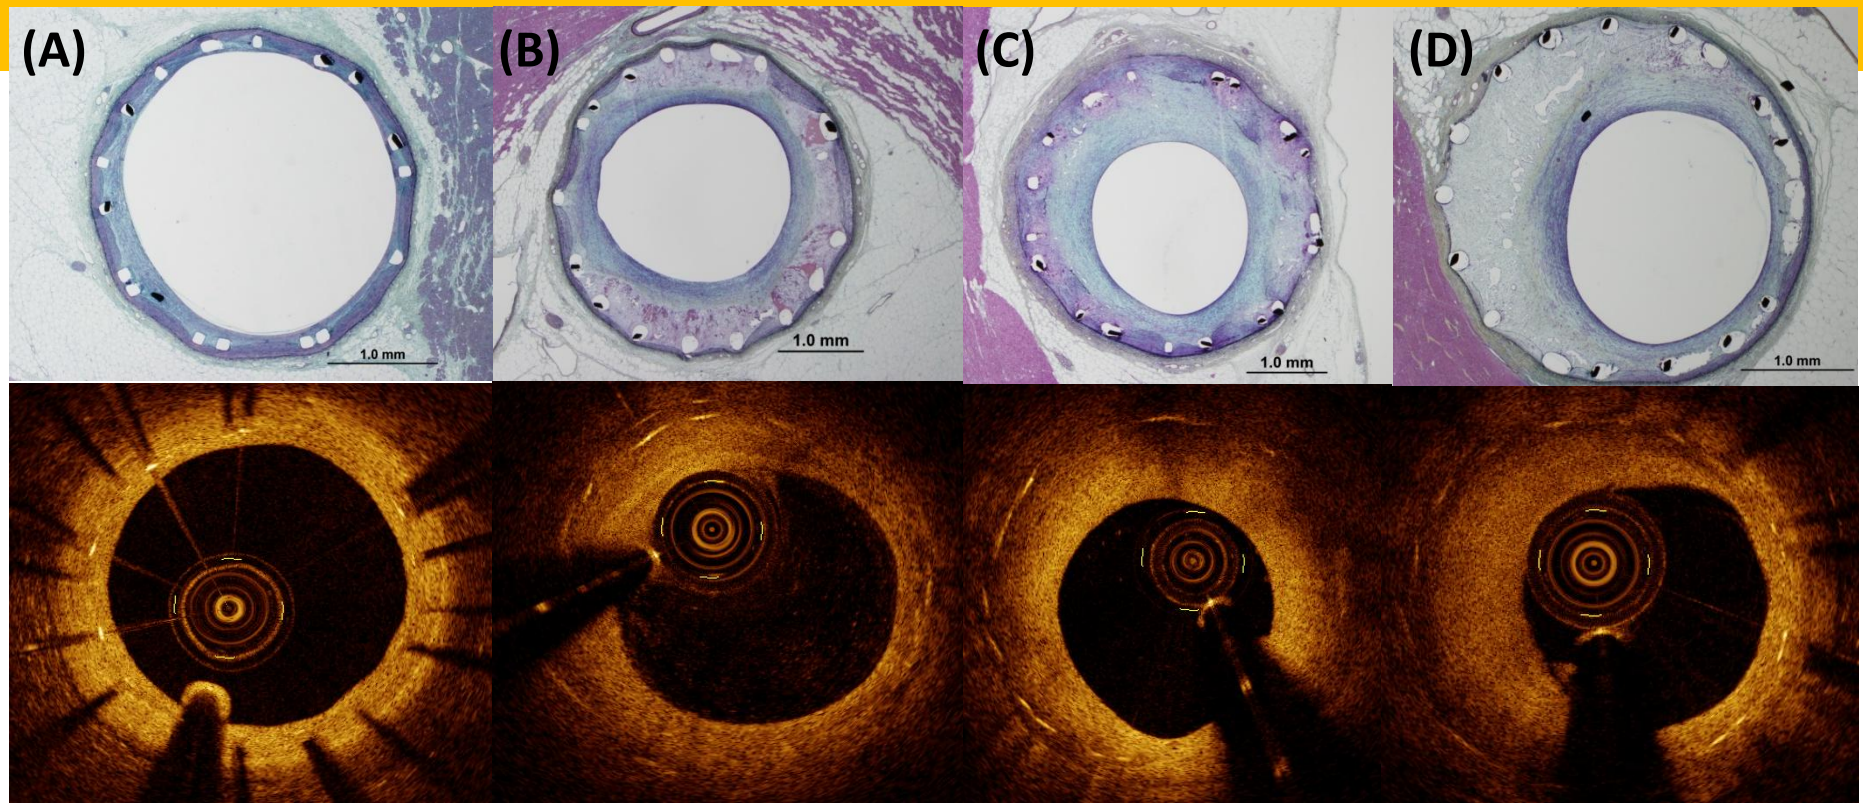
Pattern of Restenotic Tissue



Kim JS, Hong MK , et al. J Am Coll Cardiol Img 2012



Representative images of OCT and histologic sections.

(A) **Homogeneous** neointimal pattern in OCT has a collagen rich neointima (bluish color) (B) **heterogeneous** neointimal pattern shows lots of loose connective tissue (grey color) and fibrin (pink color) (C) **layered neointimal** pattern shows thick neointima, external elastic laminal rupture and peristrut inflammation (D) **neovascularization** is shown in the middle of neointima.

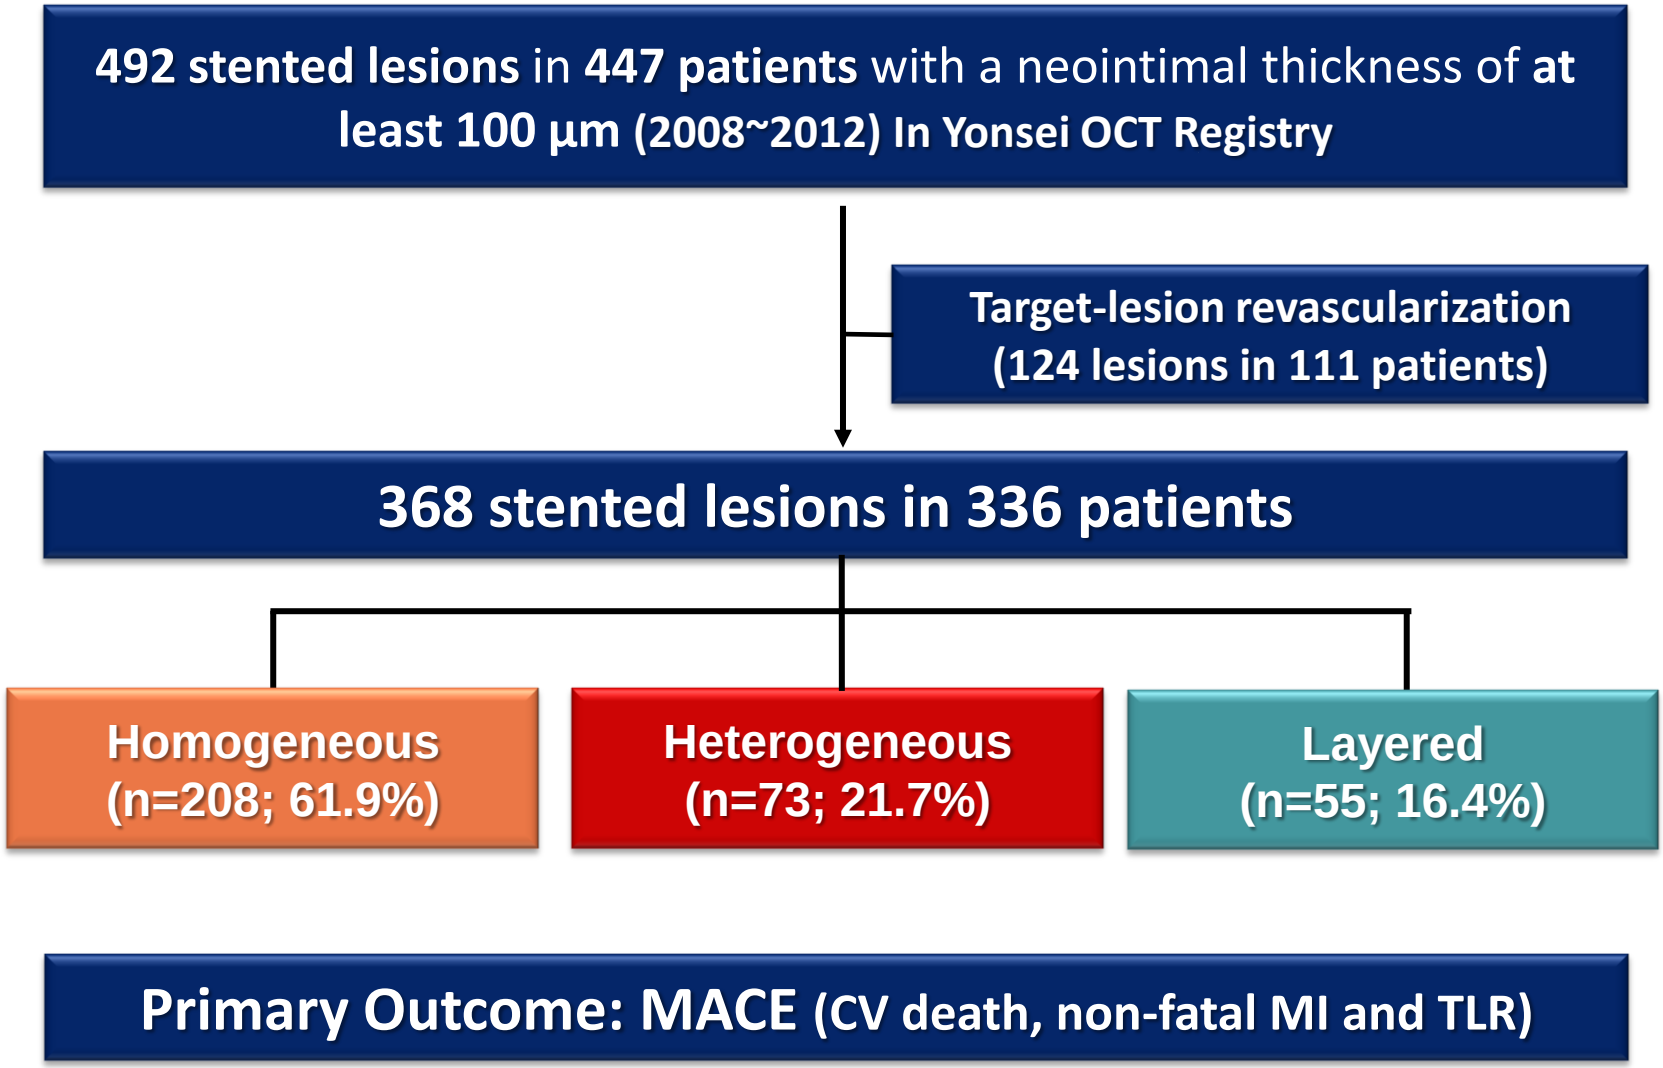
Kim JS, Granada JF, et al. Eur Heart J Cardiovasc Imaging 2013

Background

- However, the relationship between different OCT-based neointimal characteristics and clinical outcomes has not been investigated.

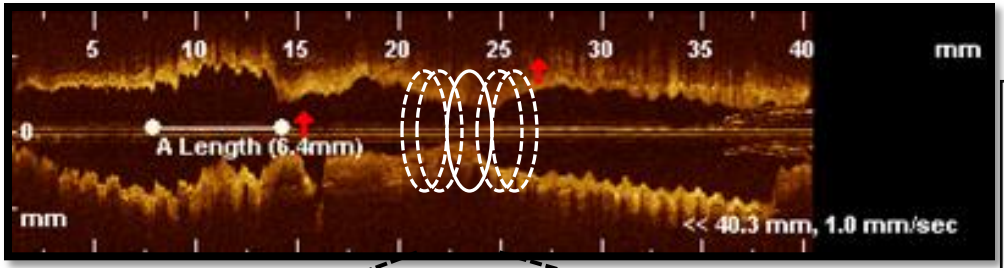
- Therefore, the aim of this study was to find out the correlation between in-stent neointimal characteristics as assessed by OCT and clinical outcomes.

Methods



492 stented lesions in 447 patients with a neointimal thickness of at least 100 µm (2008~2012) In Yonsei OCT Registry
Target-lesion revascularization (124 lesions in 111 patients)
368 stented lesions in 336 patients
Homogeneous (n=208; 61.9%)
Heterogeneous (n=73; 21.7%)
Layered (n=55; 16.4%)
Primary Outcome: MACE (CV death, non-fatal MI and TLR)

Methods



368 stented lesions with a neointimal thickness of **at least 100 μm in 5 consecutive CS** around MLA were assessed.

(A) Homogeneous pattern : an uniform signal-rich band without focal variation or attenuation.

(B) Heterogeneous pattern : focally changing optical properties and various backscattering patterns.

(C) Layered pattern : layers with different optical properties, namely an adluminal high scattering layer and abluminal low scattering layer.

Baseline characteristics

	Homogeneous (n=208)	Heterogeneous (n=73)	Layered (n=55)	p

Limitation

- Only patients with stented lesion ≥100 μm of neointimal thickness were included in this study.
- The neointimal tissue characteristics need to be validated with histology and the current intravascular OCT system may be limited in its ability to properly evaluate the qualitative characteristics of the neointima.
- The interval between stent implantation and OCT examination varied within the study population because of retrospective study.

Conclusion I

- This is the first study to investigate the clinical significance of neointimal tissue patterns.

- The occurrence of heterogeneous neointima was significantly associated with both older age and initial clinical presentation of acute coronary syndrome.

- MACEs occurred more frequently in patients with heterogeneous pattern compared with those with Homogeneous or layered pattern.

Conclusion II

- Heterogeneous pattern of neointima and minimal lumen CSA on follow-up OCT examination were independent risk factor of future MACEs.

- This findings implied that although the quantitative growth of neointimal tissue were important factors for the occurrence of MACEs after stent implantation, the qualitative pattern of neointimal characteristics might be also a possible prognostic parameter.

- These findings strongly suggest the need for large randomized clinical studies to validate the effect of neointimal characteristics by OCT on clinical outcome.
