It is generally accepted :
-Grayscale IVUS is limited to the detection of NC lesions;
-There is no specific ultrasonic textural patterns associated with NC.

Insights Into Echo-Attenuated Plaques, Echolucent Plaques, and Plaques With Spotty Calcification

Novel Findings From Comparisons Among Intravascular Ultrasound, Near-Infrared Spectroscopy, and Pathological Histology in 2,294 Human Coronary Artery Segments

Can Grayscale IVUS Detect Necrotic Core-Rich Plaque?

classification scheme by IVUS grayscale image characteristics should be updated on the basis of the novel findings by Pu et al. (1) on echo-attenuated plaque.

I read with great interest the paper by Pu et al. (1) in the *Journal* and congratulate the investigators on an excellent study, which contributes greatly to our current knowledge of intravascular ultrasound (IVUS). It is generally accepted that grayscale IVUS is limited to the detection of lipid-rich necrotic core lesions, and there is no specific grayscale ultrasonic signature associated with necrotic core. However, Pu et al.'s (1) IVUS histological validation study of 2,294

REFERENCES

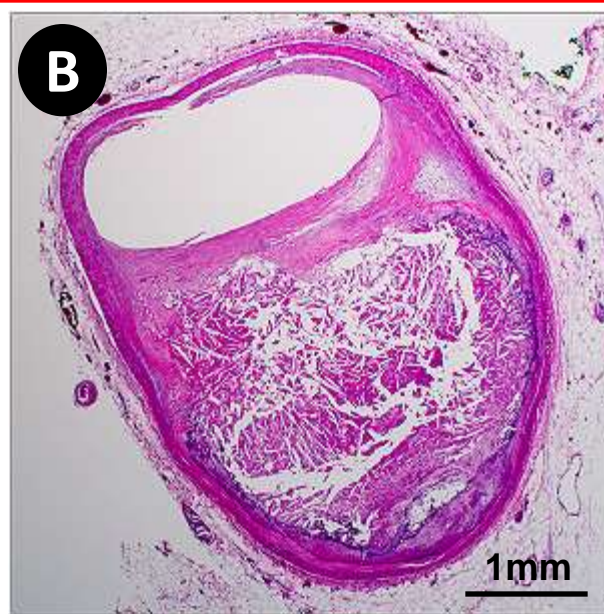

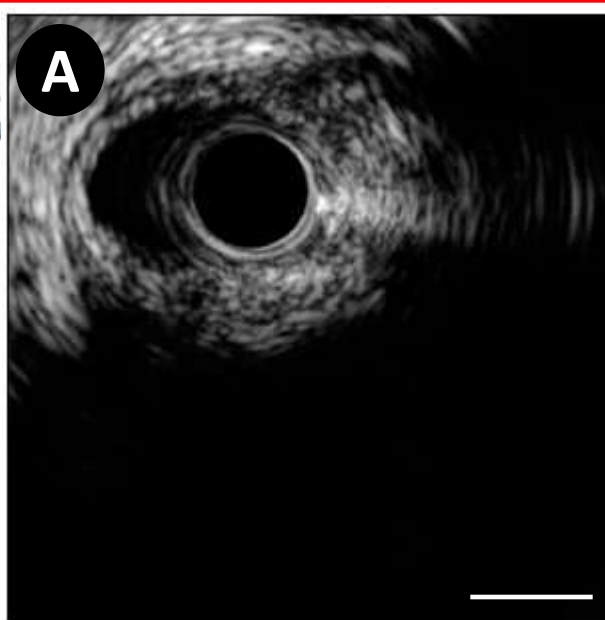

Echo-attenuated plaque a unique IVUS signature

Echo-attenuated signature - defined as the absence of ultrasound signal behind plaque that was either hypoechoic or isoechoic to reference adventitia, but without bright calcium

Arc of Echo-attenuated plaque

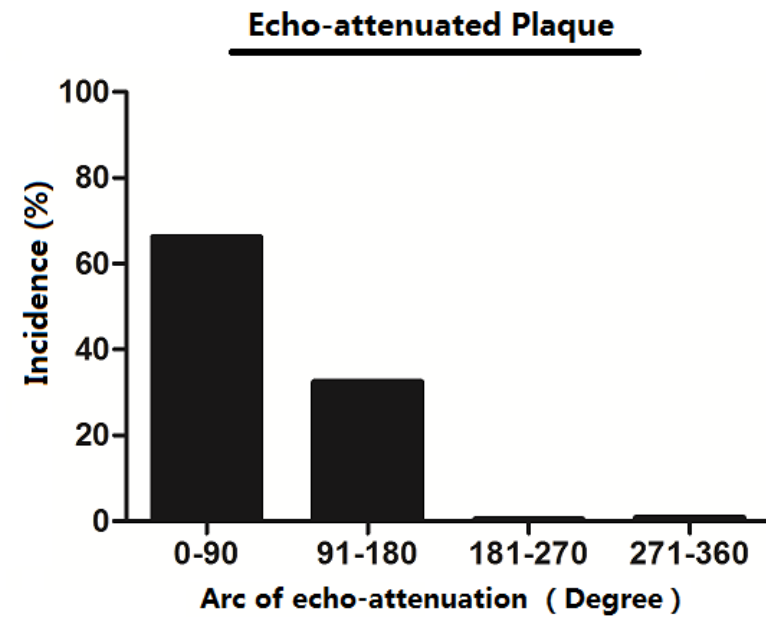

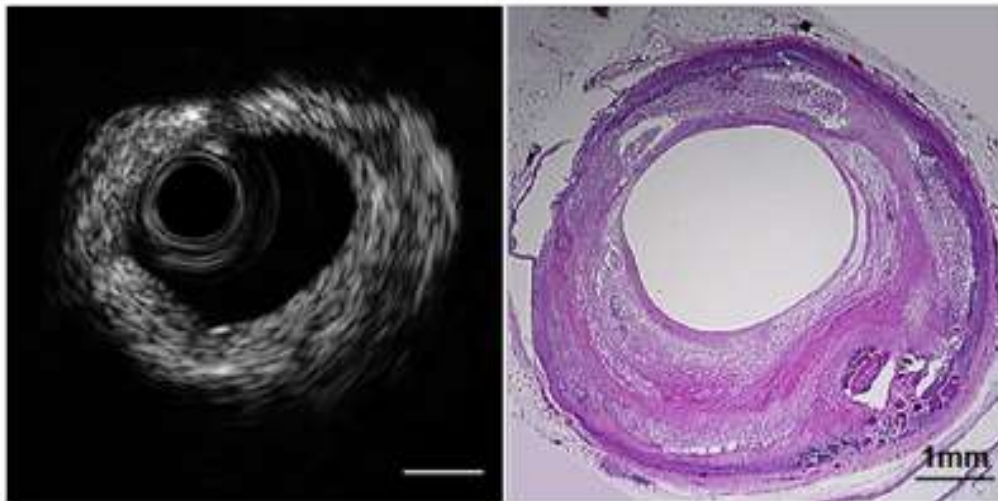

A

Echo-attenuated Plaque (Arc=30°)

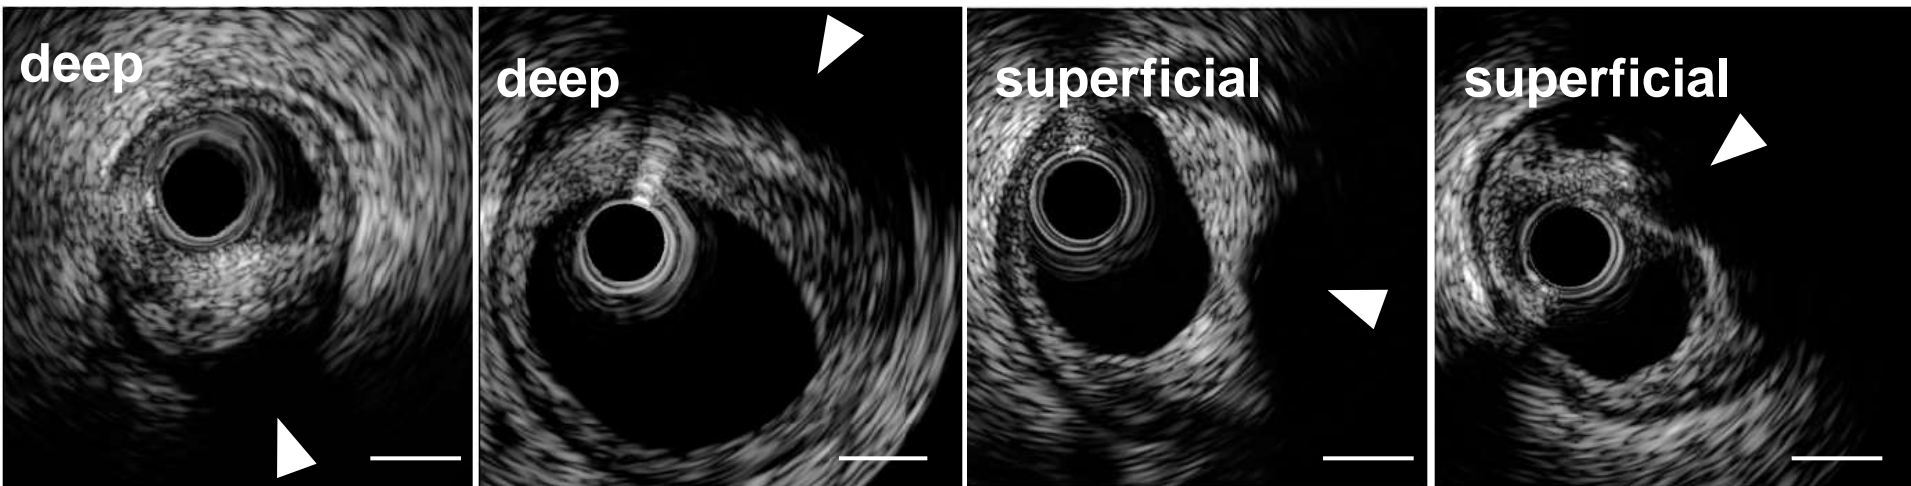

B

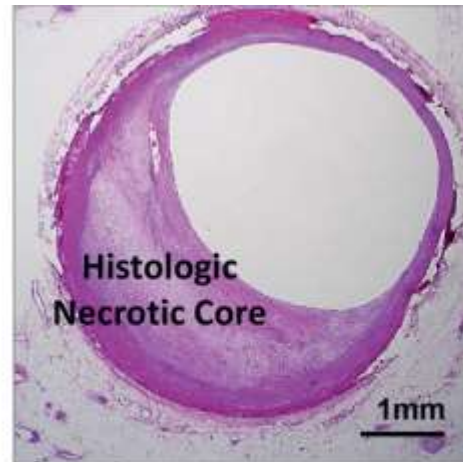

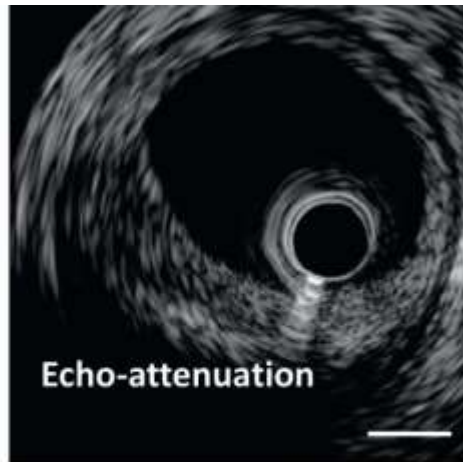

Echo-attenuated Plaque (Arc=360°)

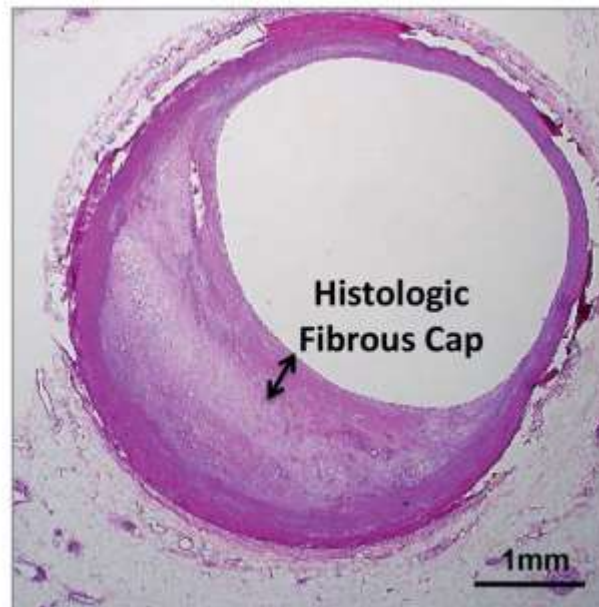

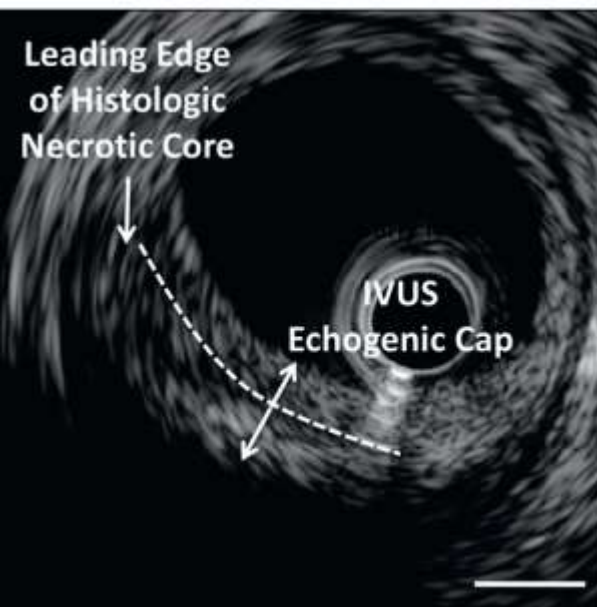

Echo-attenuation with superficial location is a reliable IVUS signature for high-risk plaque containing a large necrotic core

The Location of Histologic NC in Echo-Attenuated Plaque

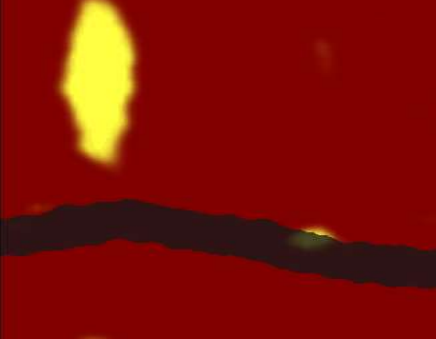

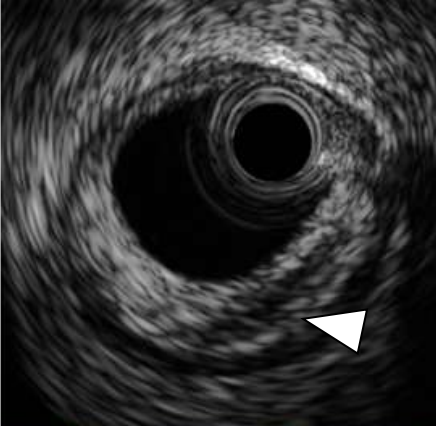

***IVUS:
Thickness of
“echogenic cap” of
echo-attenuated
plaque***

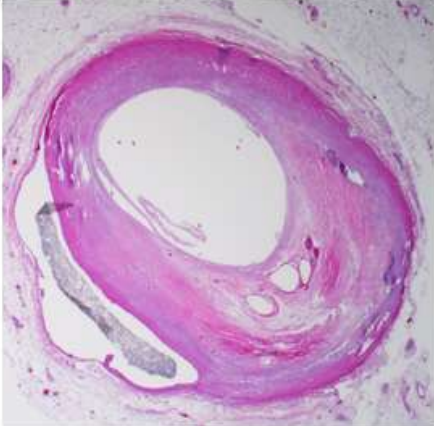

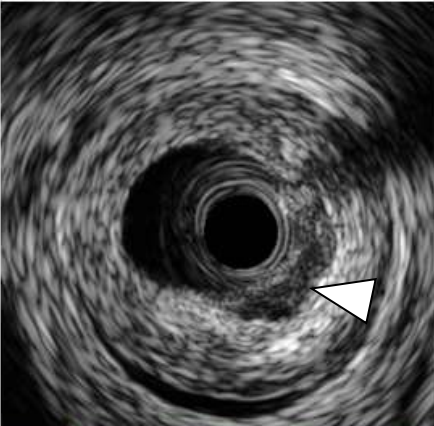

***Pathology:
Thickness of the
histologic fibrous
cap covering the
NC***

Echo-lucent plaques

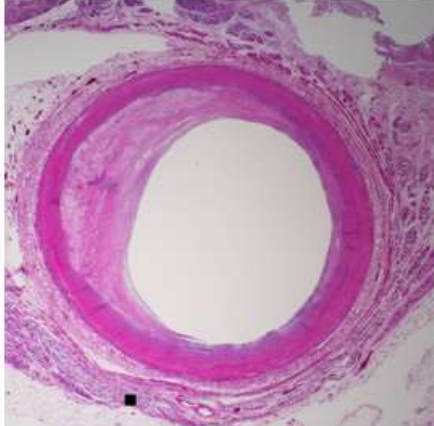

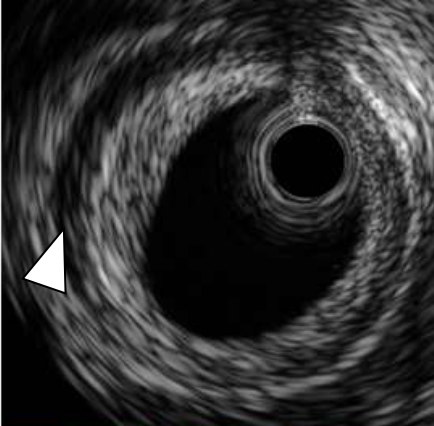

IVUS:EP (superficial)
Path: Late FA (Necrotic Core)

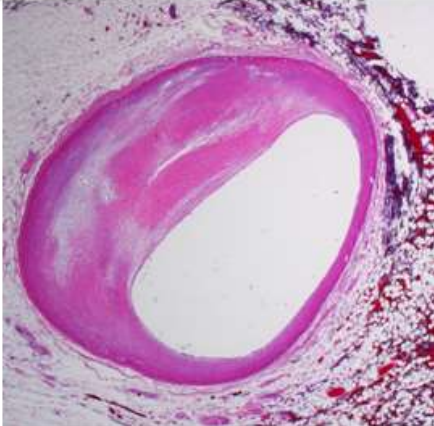

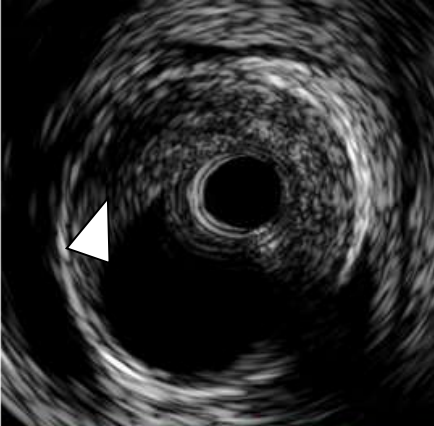

IVUS:EP (superficial)
Path: Bland fibrous (angiogenesis)

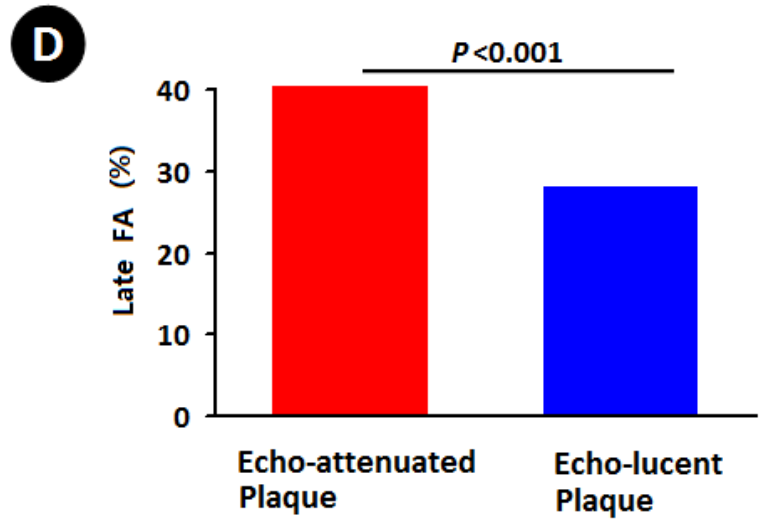

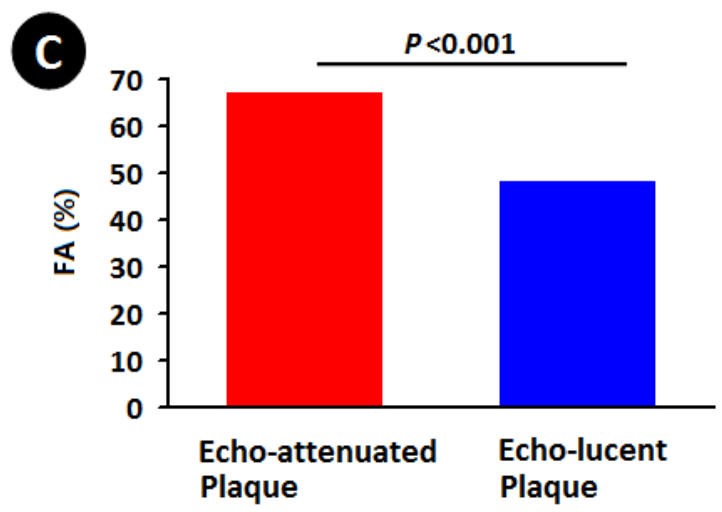

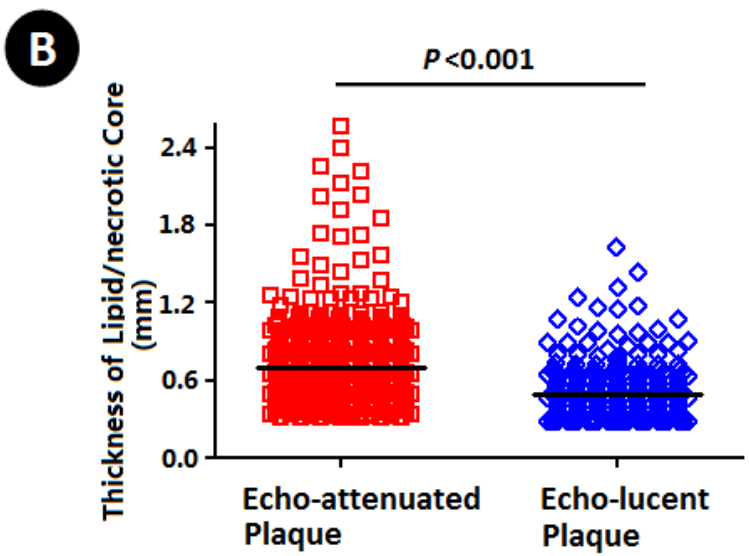

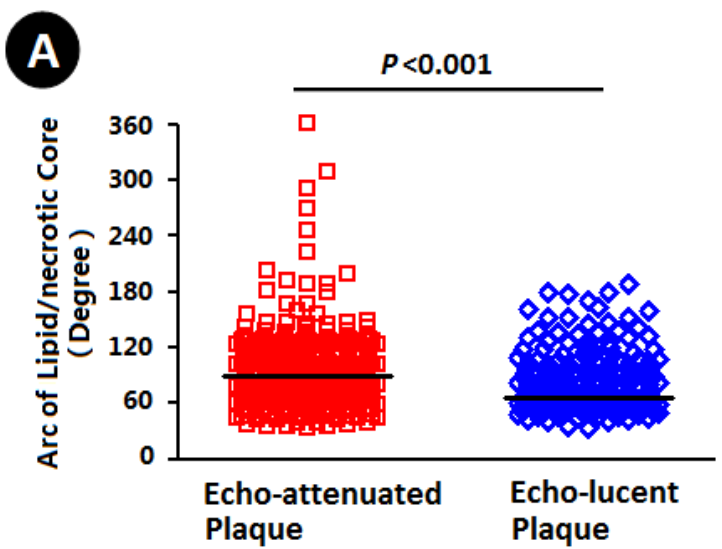

IVUS:EP (deep)
Path: PIT (lipid pool)

IVUS:EP (deep)
Path: Bland fibrous (angiogenesis)

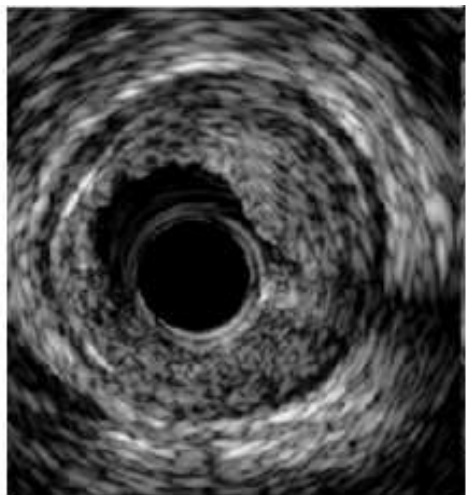

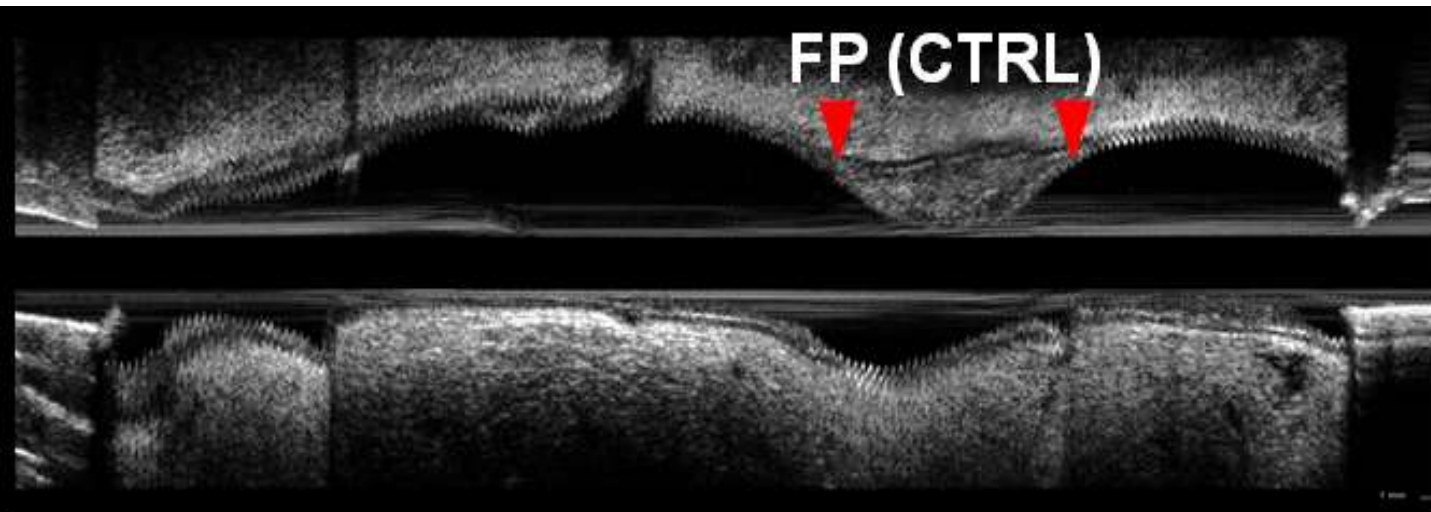

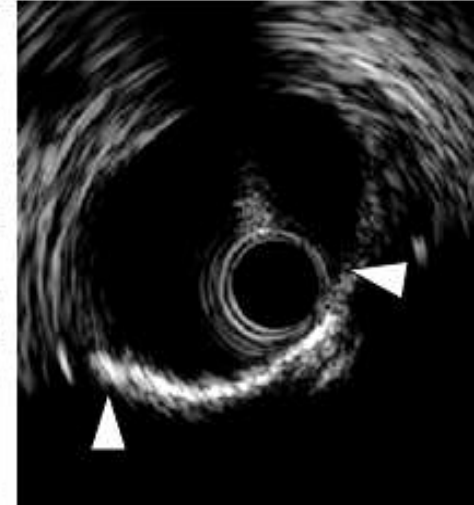

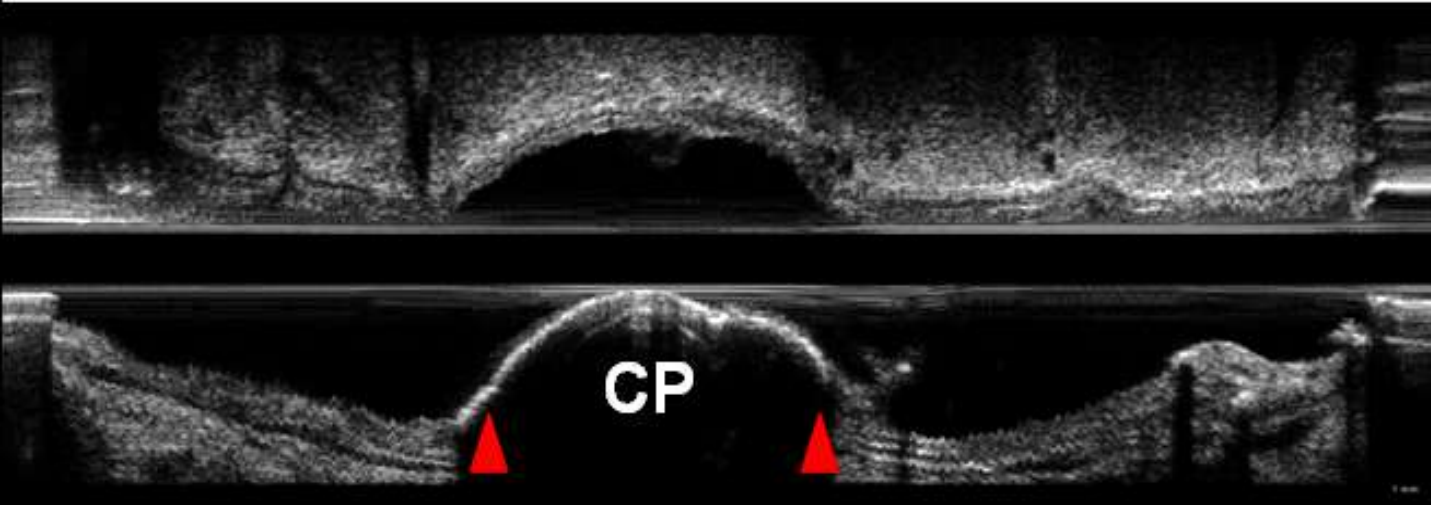

Compared with echo-attenuated plaques, echolucent plaques associated with smaller NIRS- LCP

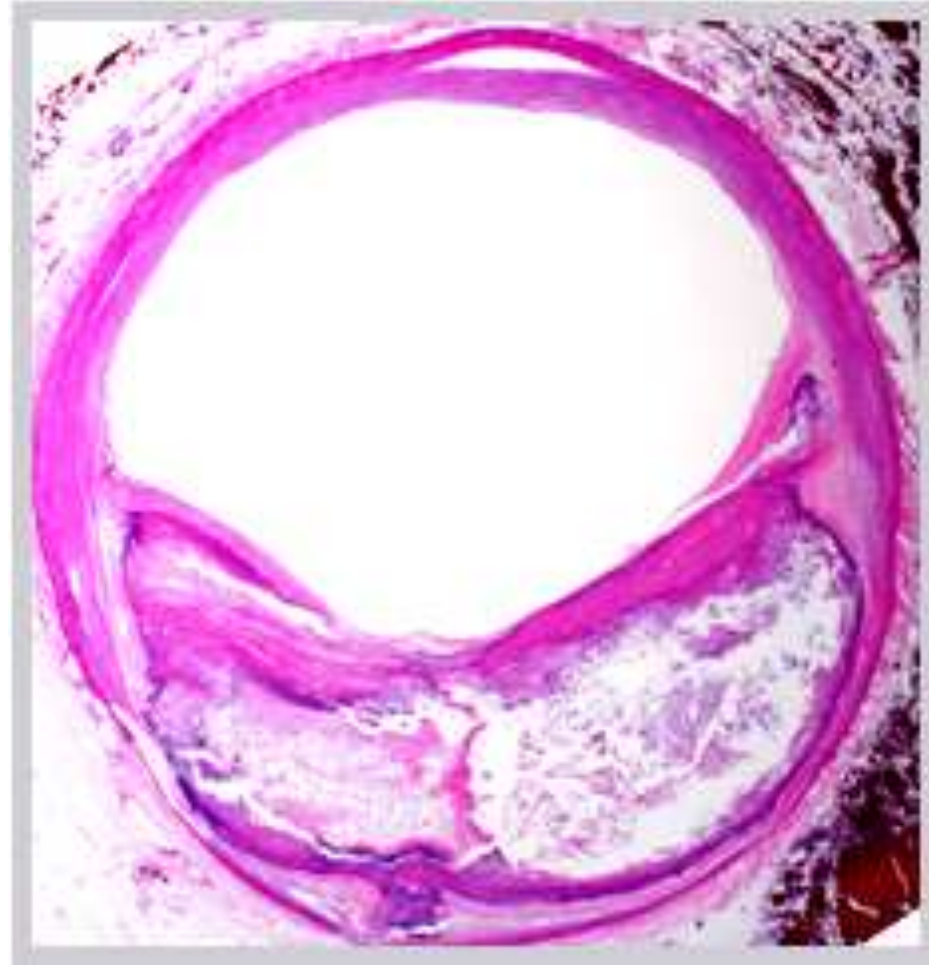

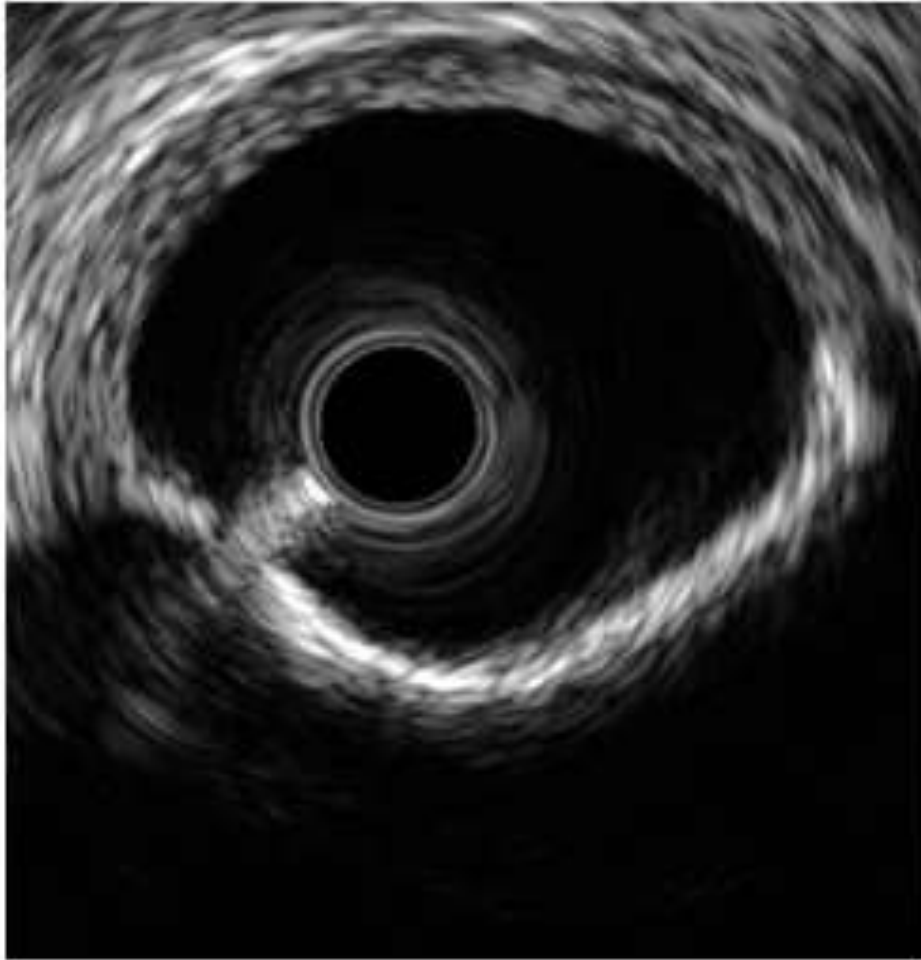

What is behind the Calcium?

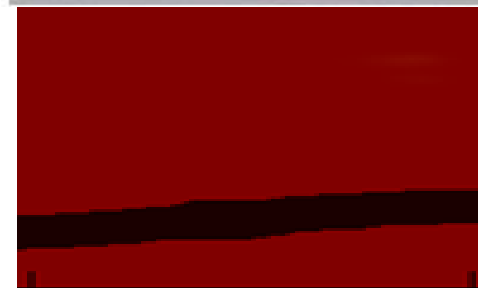

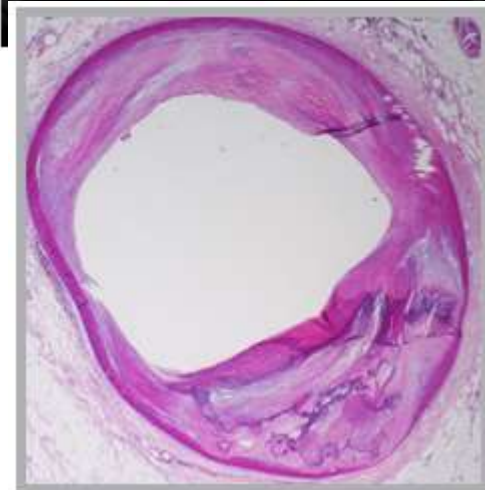

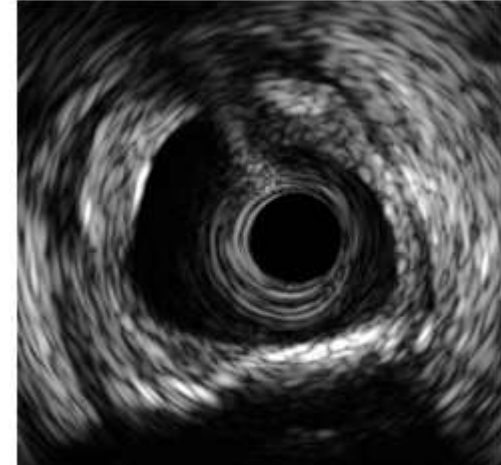

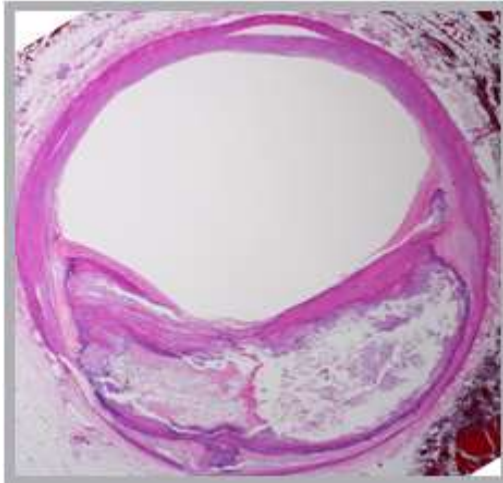

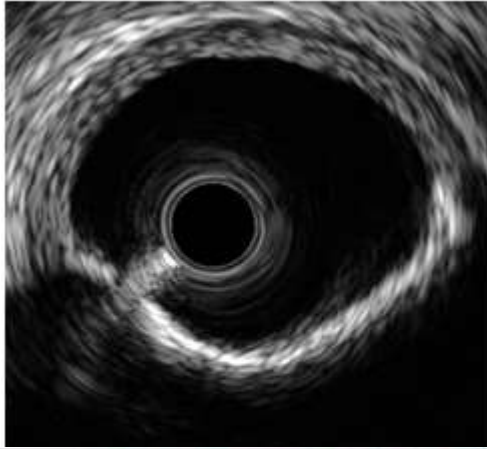

Limitation of the IVUS: can not penetrate into Calcium

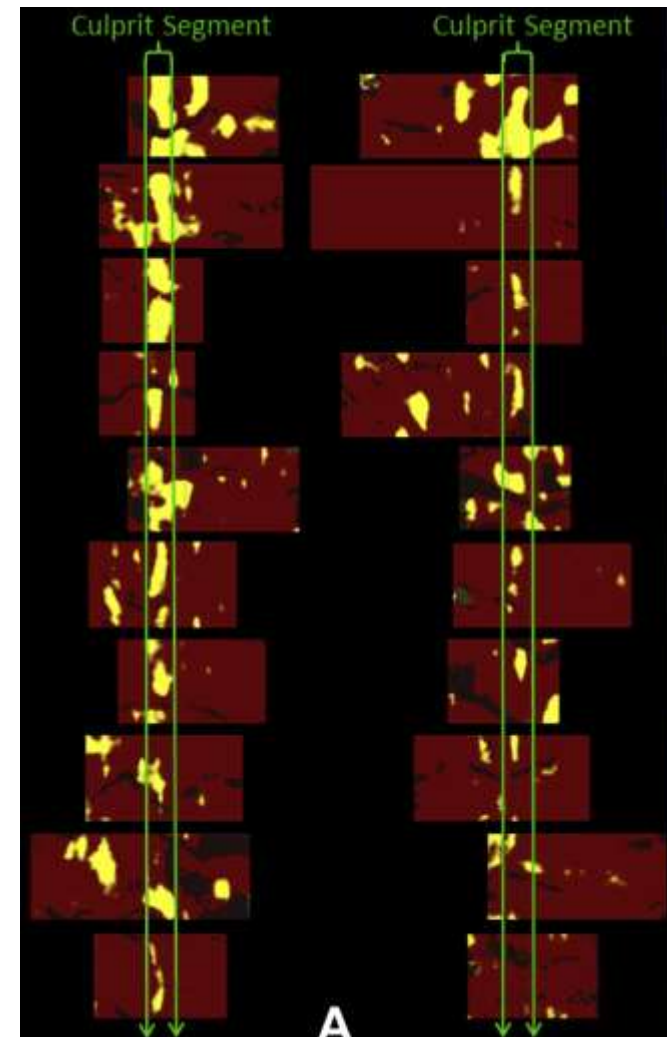

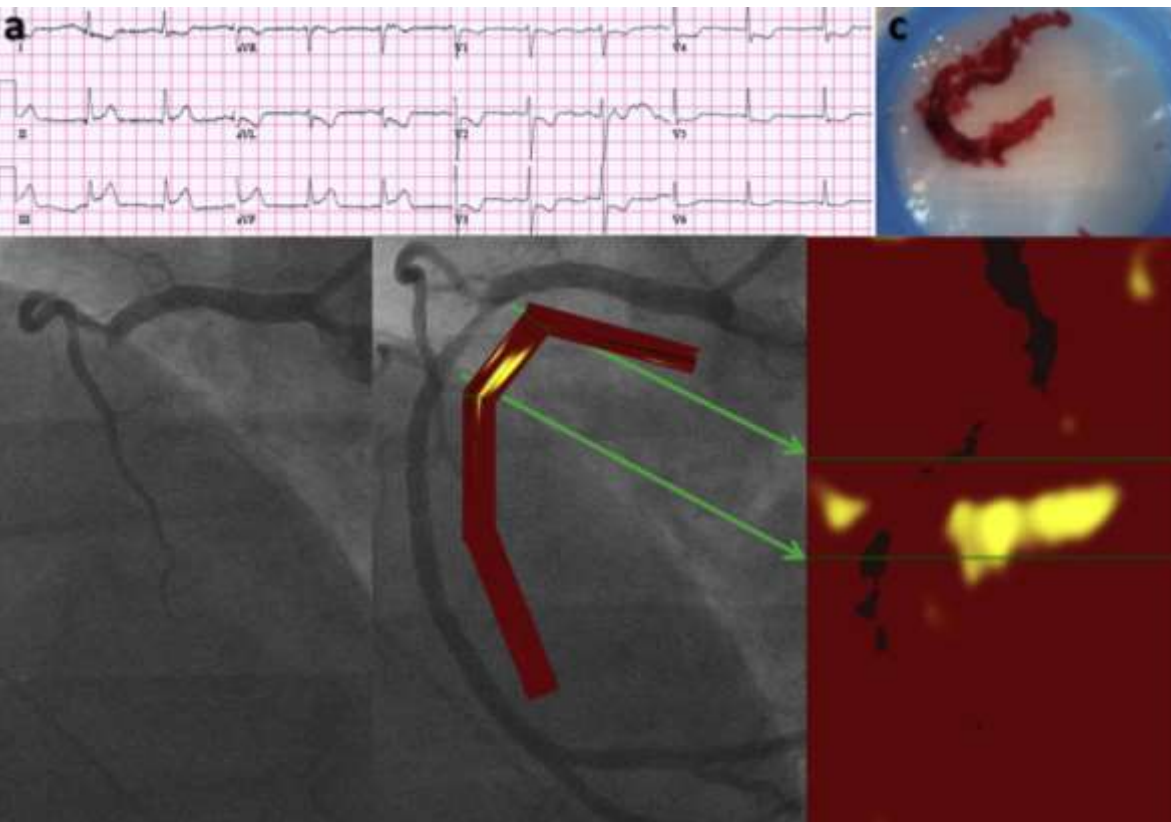

Behind Calcium, could be a very big NC
Rotation for Calcified stenosis : No reflow

NIRS could “see” calcified plaque with/without NC

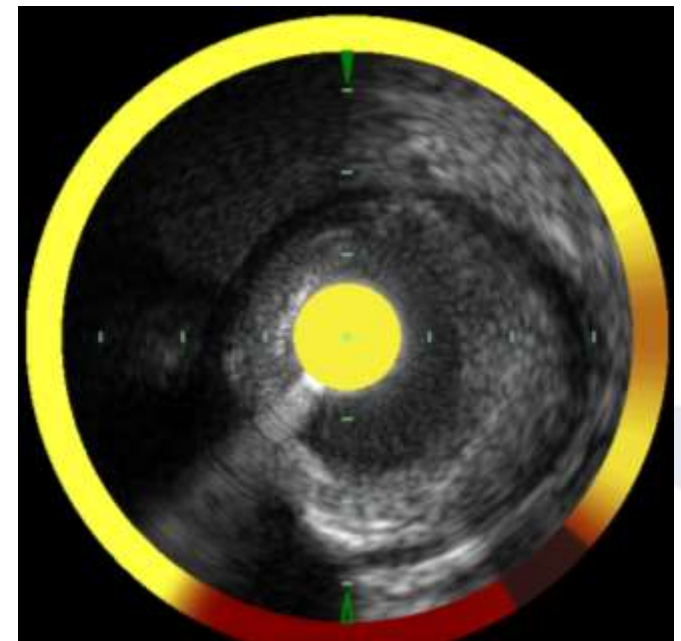

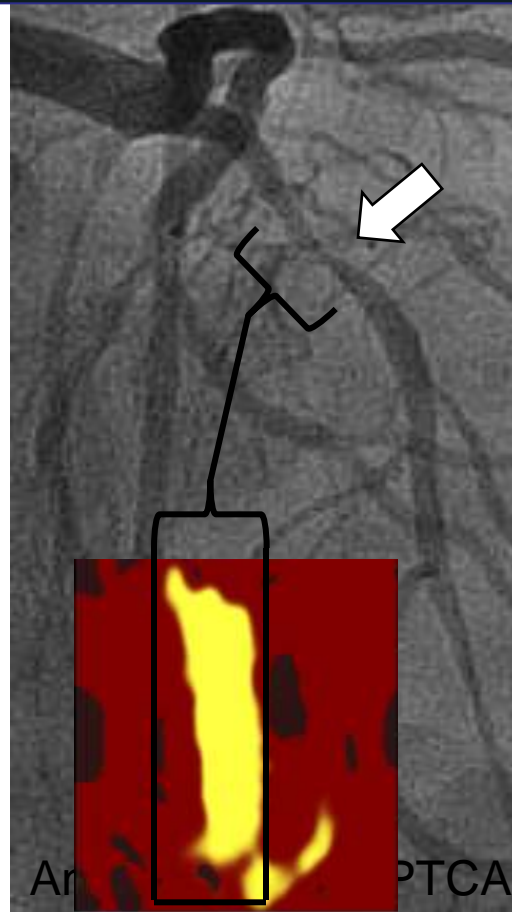

Culprit Lesions in STEMI: Insights from Near-infrared Spectroscopy

Why might a large lipid burden be important?

35 year old male with sudden cardiac arrest while mowing his lawn.

maxLCBI_{4mm} = 813

Plaque burden = 67%

Echo-attenuated plaque !

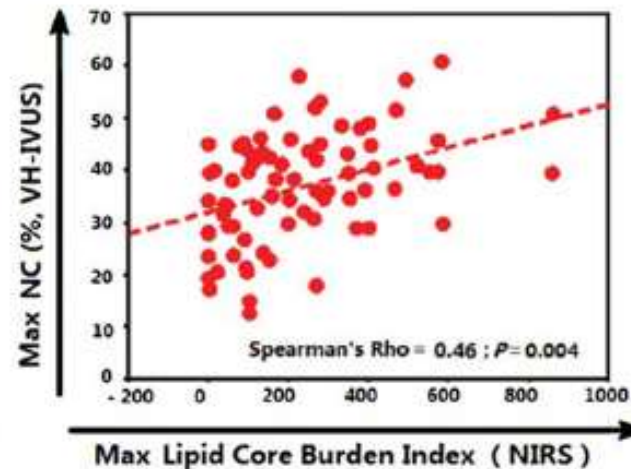

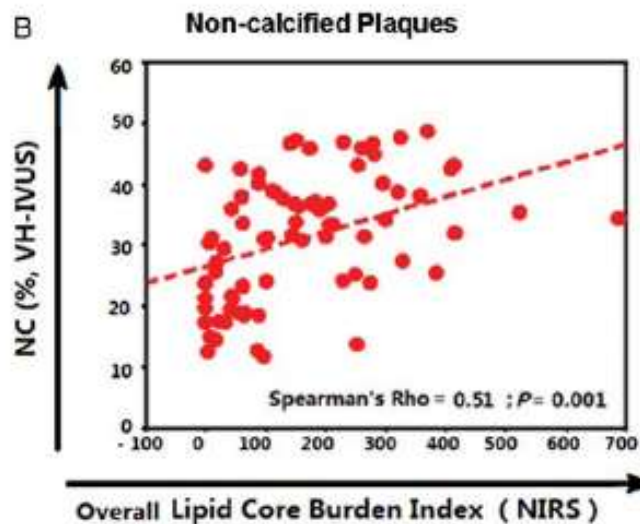

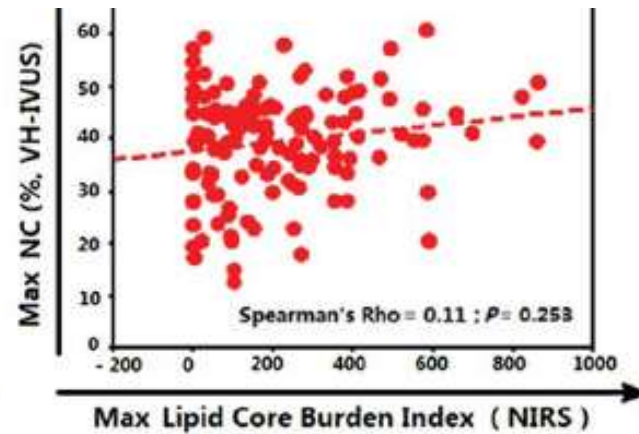

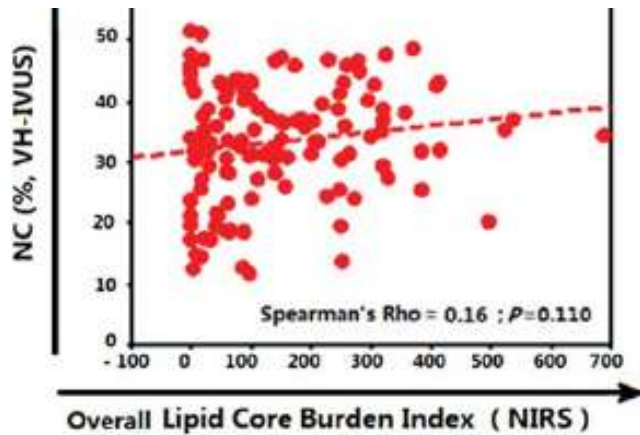

Attenuated plaques

Grayscale-IVUS-detected attenuated plaques indicated the presence of NIRS-detected LCP

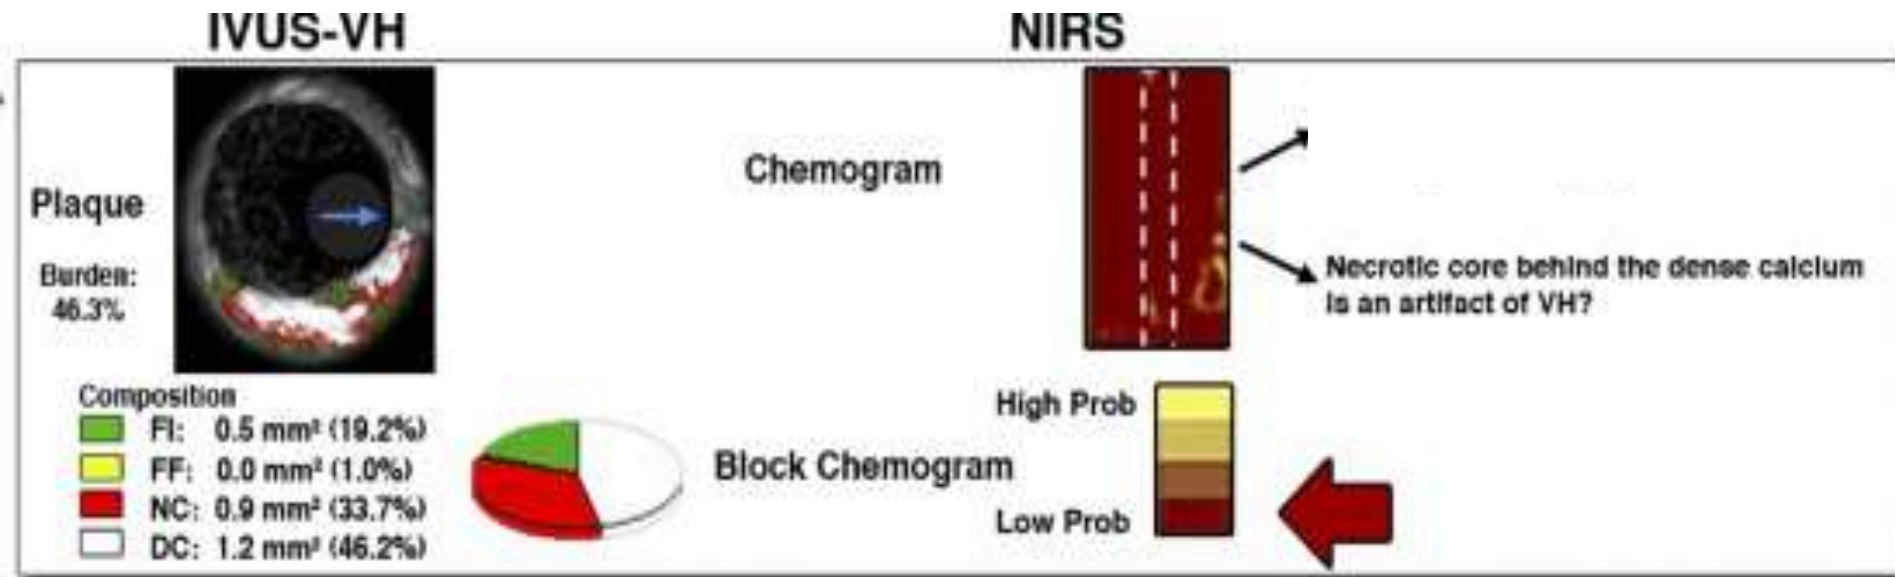

For Calcified Plaques, an interesting finding -

*A positive relationship between VH-detected NC and NIRS-detected LCP in non-calcified plaques **but not in calcified plaques** - Why?*

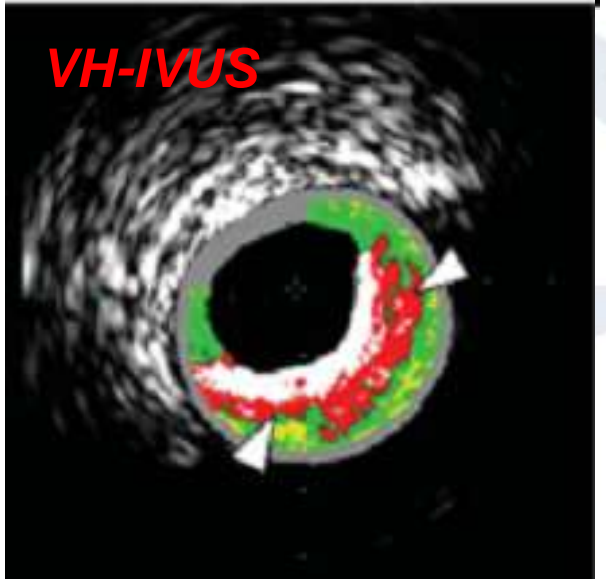

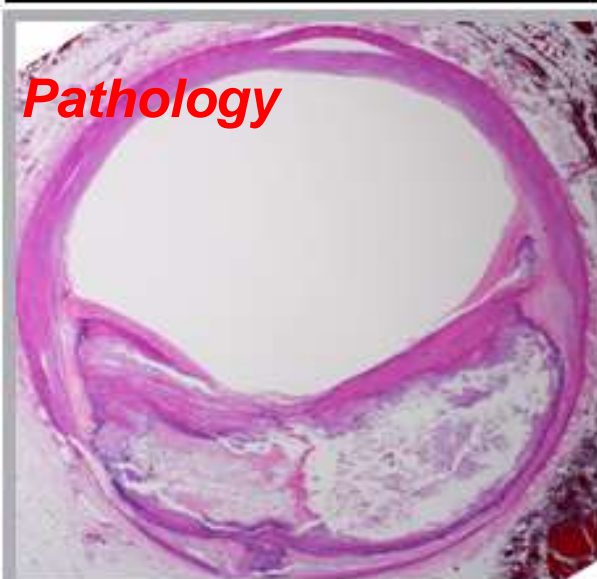

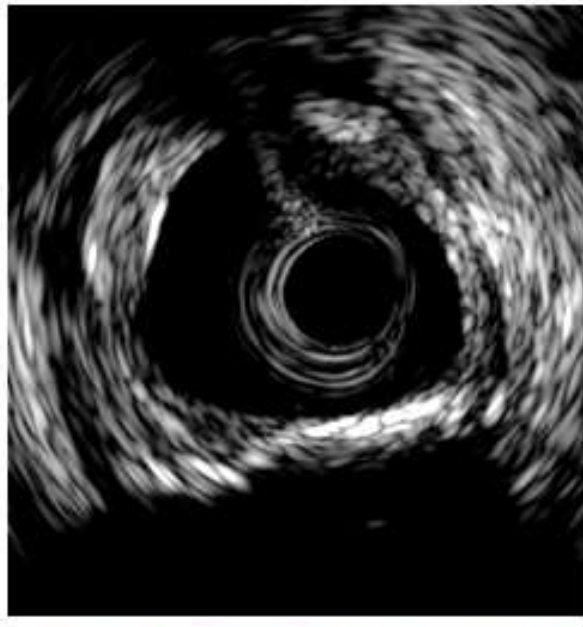

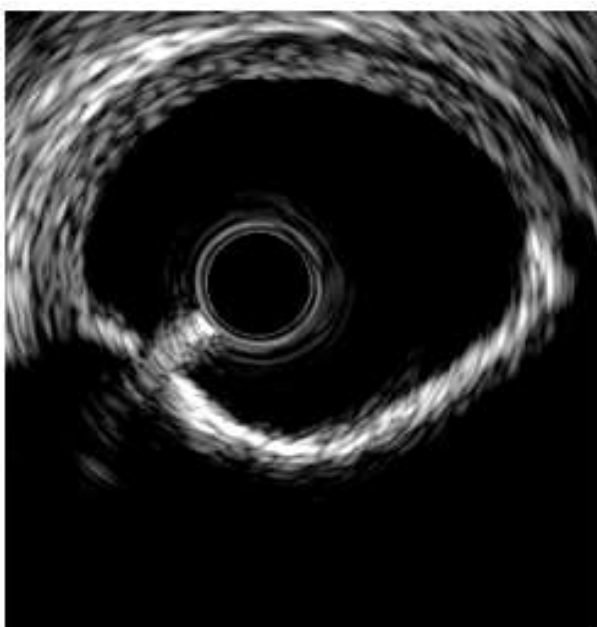

VH-IVUS overestimation of NC content in the presence of calcification

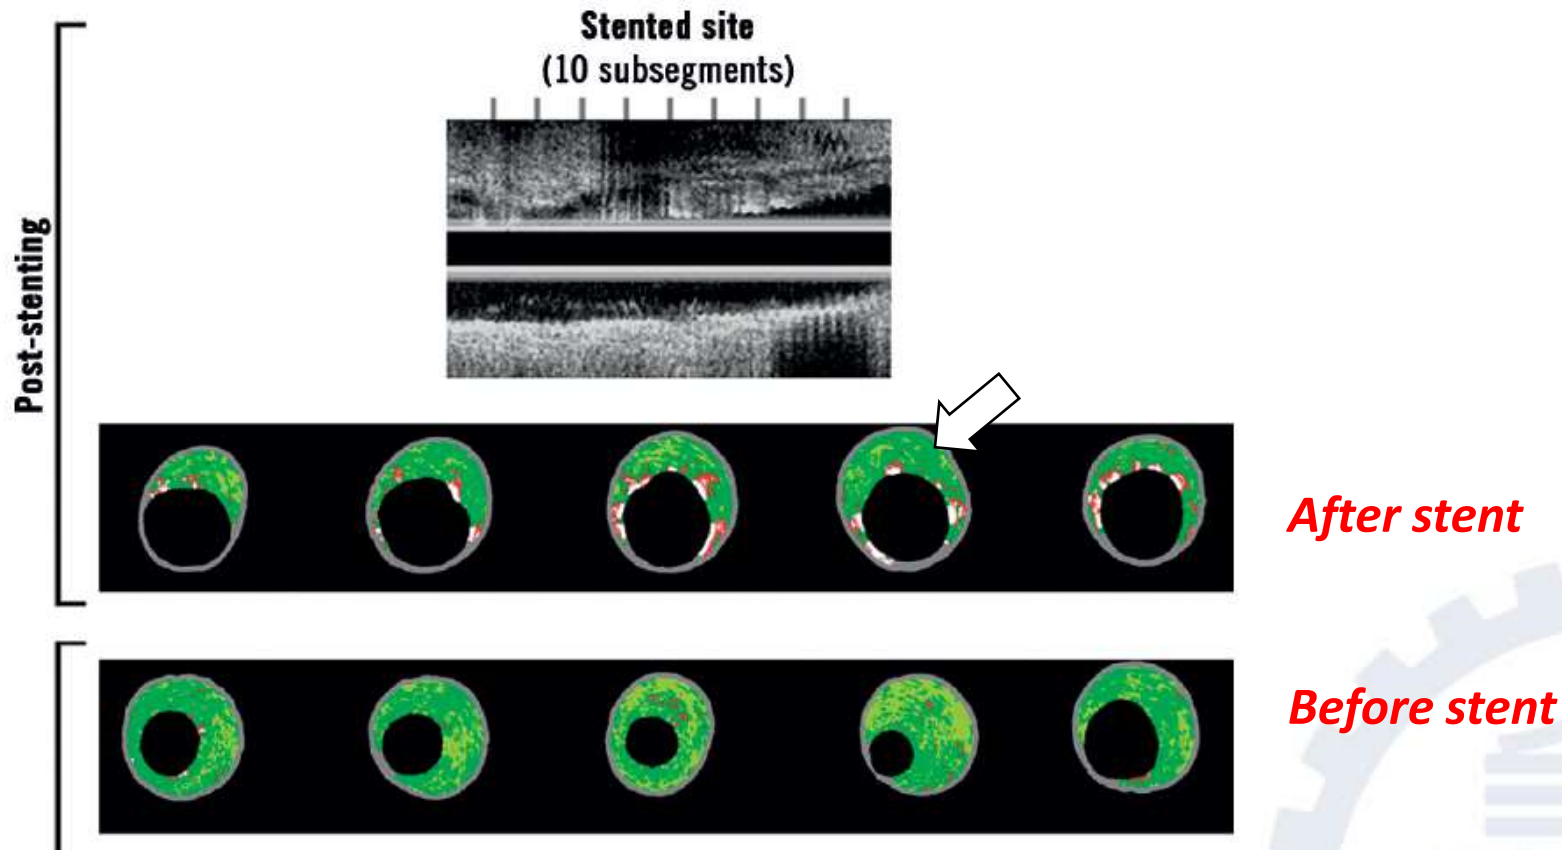

NIRS could “see” calcified plaque with/without NC

VH-IVUS could not “see” calcified plaque with/without NC

VH-IVUS always put red “necrotic core” behind the calcium

Caution should be taken in the VH-IVUS assessment of NC in vessels with heavy calcification

Artificial addition of calcium-like elements to the atherosclerotic plaque led to an increase in necrotic tissue in virtual histology that is probably artefactual

Take Home Message

- ④ Echo-attenuated signature, in particular that with superficial location, indicated a high-risk plaque containing a large NC.
- ④ VH-IVUS overestimation of NC content in vessels with heavy calcification. Caution should be taken.
- ④ NIRS can differentiate calcified plaques with/without NC, and differentiate “True” or “false” AP/EP, thus might improve the tissue characterization of coronary plaques.
