#### CABG Again Outshines Stenting for Some Patients With Coronary Artery Blockage

#### Mike Mitka, MSJ

LOS ANGELES—A study of patients with diabetes in need of multivessel revascularization has shown that coronary artery bypass graft (CABG) surgery produces better outcomes than percutaneous coronary intervention (PCI). The study, highlighted here in November during the annual Scientific Sessions of the American Heart Association (AHA), adds to the growing list of investigations showing superiority of CABG over PCI in a variety of patient populations.

Yet mounting evidence suggests that PCI continues to be performed at rates higher than is appropriate. So why does it remain difficult for interventional cardiologists to embrace this corner of the evidence-based medicine world?

At the AHA meeting, attendees heard the results from the Future Revascularization Evaluation in Patients With Diabetes Mellitus: Optimal Management of Multivessel Disease (FREEDOM) trial. The FREEDOM researchers randomized 1900 patients with diabetes and

"CABG surgery is the preferred intervention for patients with diabetes and multivessel disease," said Valentin Fuster, MD, PhD, senior author of FREEDOM

New findings suggest that coronary artery bypass graft surgery produces better outcomes than stenting in patients with diabetes who require multivessel revascularization.

103 549 patients who underwent PCI for treatment of 2-vessel or 3-vessel coronary artery disease without acute myocardial infarction from 2004 through 2008 (Weintraub WS et al. N Engl J Med. 2012;366[16]:1467-1476).

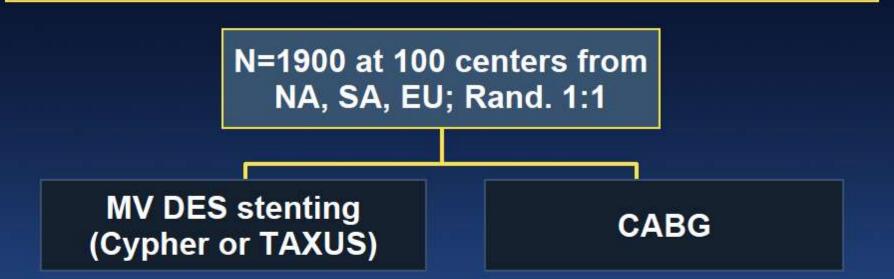

William S. Weintraub, MD, one of ASCERT's principal investigators and director of the Christiana Center for Outcomes Research in Wilmington, Del, said the FREEDOM trial should reinforce the superiority of CABG in revascularization of complicated patients. "Overall, surgery has been in decline for a number of years, and we've moved to less invasive procedures fairly easily," said Weintraub in an interview. "But with FREEDOM, you are moving the needle back toward surgery."

Fred H. Edwards, MD, another principal investigator with ASCERT and emeritus professor in the department of surgery at the University of Florida Academic Health Center in Jacksonville, said his trial and FREEDOM should give clinicians the evidence they need to make better-informed deci-

## **FREEDOM** SAFETY OUTCOMES (30 DAYS)

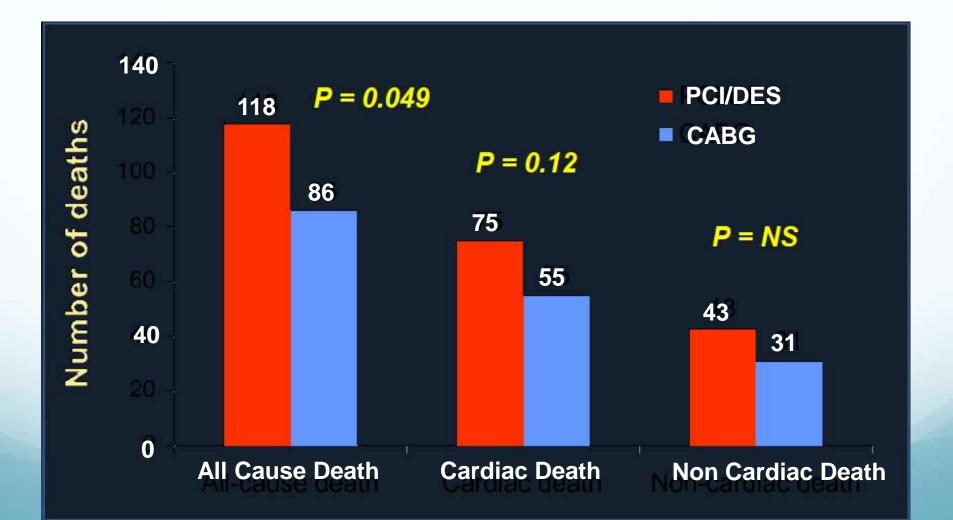

### **FREEDOM** Primary Endpoint: Death, Stroke, or MI

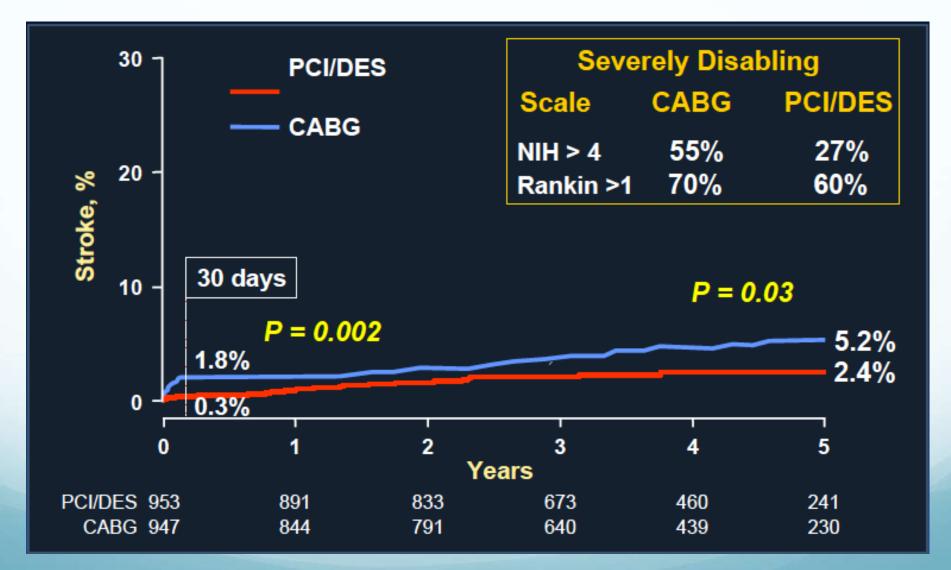

### **FREEDOM** All Cause Mortality

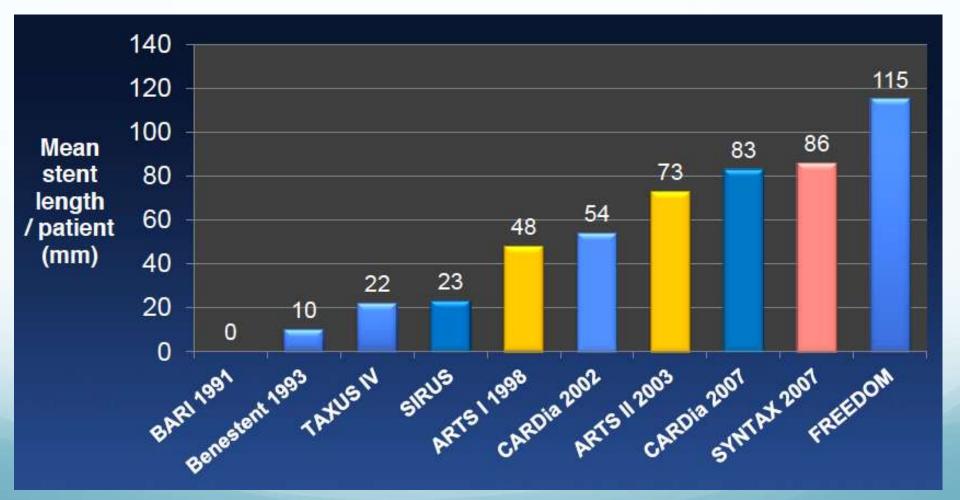

### **FREEDOM** All Cause Mortality

# Stroke

### Stent Usage Per Patients A Marker of Lesion Complexity OR Over-Stenting?

# Conclusions

- The most contemporary RCTs of PCI vs. CABG in patients with MVD and diabetes mellitus do not show a consistent advantage for CABG in reduction of cardiac mortality, particularly in patients with lower/intermediate SYNTAX score.
- With current DES, the benefits of PCI compared to CABG in terms of lesser invasiveness, lower major procedural complications, better early QOF, and lower stroke rate outweight the higher rate of repeat revascularization, as long as mortality is not increased.
