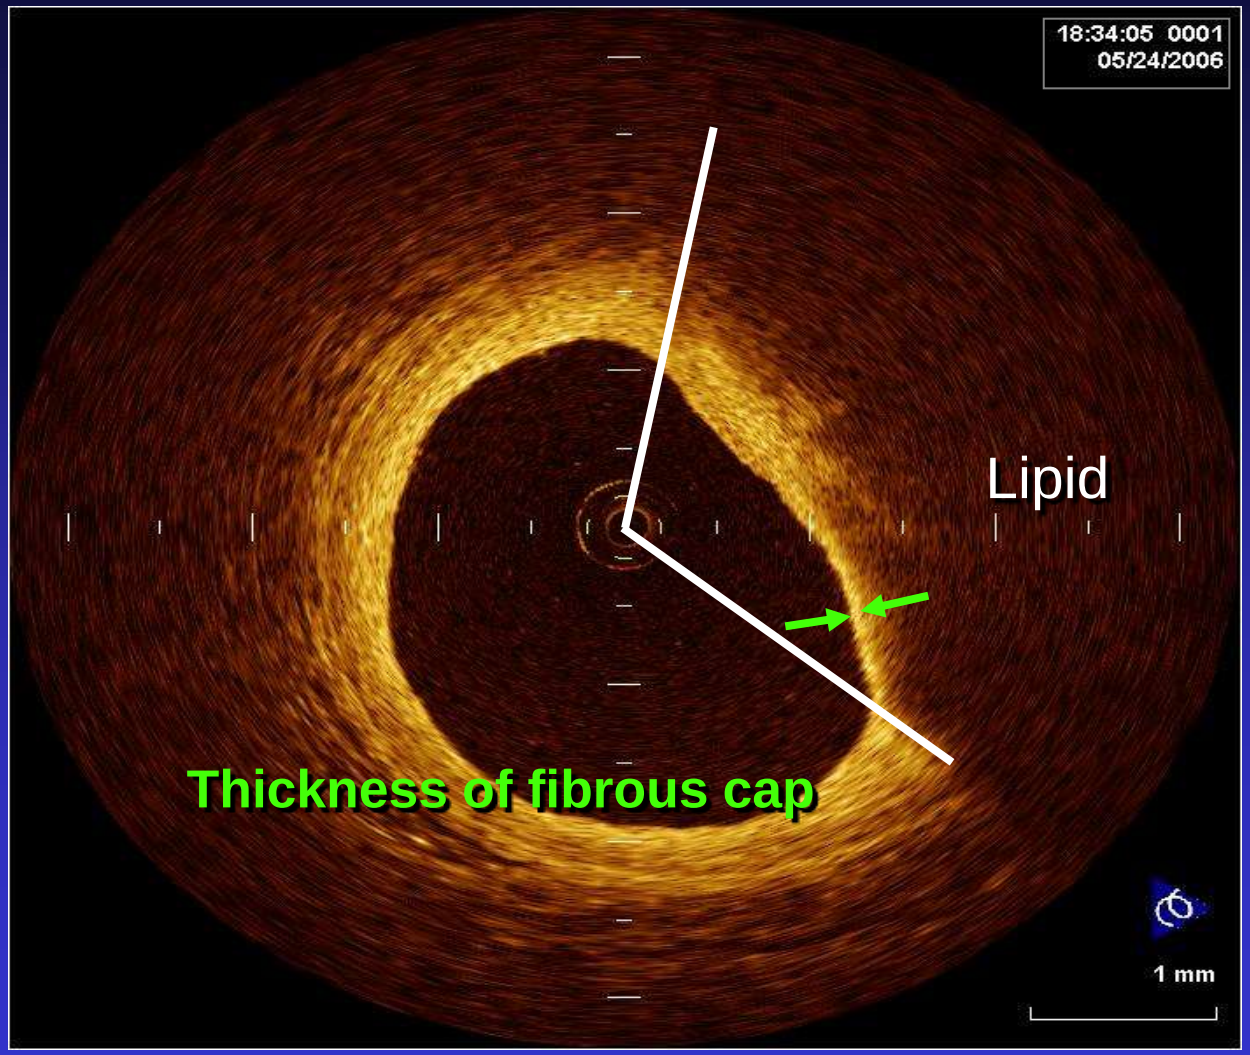
Thin-capped Fibroatheroma (TCFA)



TCFA was defined as a plaque with lipid content in more than 2 quadrants and the thinnest part of a fibrous cap measuring less than 65 μm by histology.

The cap thickness is measured from the surface of the lumen to the portion just starting the attenuation.

TCFA is thought to be a plaque prone to rupture and vulnerable

Non-ST elevation acute coronary syndrome

ABSTRACT

Background: Autopsy studies have reported that rupture of a thin-cap fibroatheroma and subsequent thrombus formation is the major mechanism leading to acute coronary syndrome (ACS). However, it is not clear why only some plaque ruptures lead to ACS. Optical coherence tomography (OCT) is a high-resolution imaging modality which is capable of investigating detailed coronary plaque morphology in vivo. The objective of this study was to determine whether ruptured plaque morphology assessed by OCT differs between asymptomatic coronary artery disease (CAD) and non-ST elevation acute coronary syndrome (NSTEACS).

Methods: We examined ruptured plaque morphology using OCT in 80 patients, 33 with asymptomatic CAD and 47 with NSTEACS.

Results: The frequency of lipid-rich plaque and intracoronary thrombus was significantly lower in asymptomatic CAD than in NSTEACS (61% vs. 85%, $p = 0.013$ and 9% vs. 83%, $p < 0.001$, respectively). Although maximal ruptured cavity cross-sectional area (CSA) was similar in both groups, lumen area at the rupture site and minimal lumen area were significantly larger in asymptomatic CAD than in NSTEACS (3.78 ± 1.50 mm^2 vs. 2.70 ± 1.55 mm^2, $p = 0.003$ and 2.75 ± 0.99 mm^2 vs. 1.72 ± 0.90 mm^2, $p < 0.001$, respectively).

Conclusions: OCT revealed that the morphology of ruptured plaques differs between asymptomatic CAD and NSTEACS in terms of lumen area and the frequency of lipid-rich plaques and thrombi. These morphological features may be associated with the clinical presentation of CAD.

[c] Medical School of Athens University, Hi

ABSTRACT

Background: OCT with its unique image resolution is the ideal method to detect culprit lesion characteristics in different clinical presentations. The identification of inflammatory markers related to plaque characteristics may be of clinical importance.

Methods: Thirty-two patients with acute coronary syndromes (ACS) and fourteen patients with stable angina pectoris (SAP) were enrolled in this study. Culprit lesion morphology was assessed by optical coherence tomography (OCT) in patients with ACS and SAP. The possible relations between serum levels of high sensitivity-C reactive protein (hs-CRP) and interleukin-18 (IL-18) with plaque characteristics were investigated in those patients.

Results: Plaque rupture and thin-cap fibroatheroma (TCFA) were detected more frequently in ACS patients compared with SAP patients, (78.6% vs. 14.3%, $p<0.001$, 92.9% vs. 14.3%, $p<0.001$, respectively). Higher levels of serum hs-CRP and IL-18 were found in patients with plaque rupture vs. those with no plaque rupture (median value: 19.2 mg/L vs. 1.6 mg/L, $p<0.001$ and 219.5 pg/ml vs. 127.5 pg/ml, $p=0.001$ respectively), and TCFA vs. those without TCFA (median value: 15.2 mg/L vs. 1.6 mg/L, $p=0.004$ and 209.0 pg/ml vs.153.2 pg/ml, $p=0.03$ respectively). Serum hs-CRP was the only independent predictor of plaque rupture ($p=0.02$, odds ratio 1.1, 95% confidence interval 1.0 to 1.2). A cut-off value of hs-CRP>4.5 mg/L could detect ruptured plaque with a sensitivity of 91.7% and a specificity of 77.8%.

Conclusions: OCT detected plaque rupture and TCFA more frequent in ACS patients compared with SAP. Elevated hs-CRP and IL-18 were positively related to plaque instability and rupture.

University, Tanabe, Waka

Received 30 October 2011

Aims The importance of oxidized low-density lipoprotein (oxLDL) has been implicated in the process of plaque rupture. However, few previous studies demonstrated the relationship between plaque morphology and oxLDL. We evaluated the relationship between coronary plaque vulnerability assessed by optical coherence tomography (OCT) and circulating malondialdehyde-modified low-density lipoprotein (MDA-LDL).

Methods and results OCT was used to determine plaque vulnerability in 102 patients with acute coronary syndrome (ACS; $n = 53$) and stable angina pectoris (SAP; $n = 49$). Circulating levels of MDA-LDL were measured by using enzyme-linked immunosorbent assay. Thin-cap fibroatheromas (TCFAs; defined as lipid-rich with plaque cap thickness < 65 μm) were detected more frequently in ACS than in SAP (83% vs. 16%, $P < 0.001$). The circulating levels of MDA-LDL were significantly higher in patients with ACS compared with SAP ($P = 0.008$). The levels of MDA-LDL were significantly higher in SAP patients with TCFA than those with non-TCFA ($P < 0.001$). Although the levels of MDA-LDL were not significant between ACS patients with TCFA and those with non-TCFA, patients with ruptured TCFA had higher levels of MDA-LDL compared with those with morphologically intact TCFA ($P = 0.023$). MDA-LDL levels were associated with the presence of TCFA (odds ratio, 1.45 per 10-unit increment of MDA-LDL; 95% CI, 1.24–1.68; $P < 0.001$) in multivariable logistic regression analysis.

Conclusion Circulating MDA-LDL levels might be associated with the presence of TCFA in the culprit lesion.

[e] Division of Cardiology, Nippon Medical School, Tok

ABSTRACT

Background: Relationships between plaque morphology on optical coherence tomography (OCT) and biomarker levels in the patients with acute coronary syndrome (ACS) have not been fully investigated.

Methods: ACS patients (n = 128) were prospectively enrolled and their plasma levels of soluble lectin-like oxidized LDL receptor-1 (sLOX-1), high-sensitivity C-reactive protein (hs-CRP), and high-sensitivity troponin T (hs-TnT) were measured. Another set of 20 patients with stable angina pectoris (SAP) without plaque rupture or erosion served as controls. Among 128 ACS patients, 75 patients underwent OCT procedure to evaluate culprit plaque morphology, and were categorized into two groups; ACS with plaque rupture (ruptured ACS; R-ACS, n = 54) and ACS without plaque rupture (non-ruptured ACS; N-ACS, n = 21).

Results: Levels of sLOX-1 ($p < 0.001$), hs-CRP ($p = 0.048$) and hs-TnT ($p < 0.001$) were significantly higher in R-ACS than SAP. Levels of sLOX-1 were also significantly higher in R-ACS than in N-ACS ($p < 0.001$); whereas levels of hs-CRP ($p = 0.675$), as well as those of hs-TnT ($p = 0.055$), were comparable between R-ACS and N-ACS. Comparison of receiver operating characteristic (ROC) curves among sLOX-1, hs-CRP and hs-TnT to differentiate R-ACS from N-ACS revealed that the area under the curve (AUC) values of sLOX-1, hs-CRP and hs-TnT were 0.782, 0.531 and 0.643, respectively. ROC curves, generated for these biomarkers, to differentiate ACS with thin-cap fibroatheroma (TCFA) from those without demonstrated that the AUC values of sLOX-1, hs-CRP and hs-TnT were 0.718, 0.506 and 0.524, respectively.

Conclusion: sLOX-1, but not hs-CRP or hs-TnT, can differentiate ACS with plaque rupture from those without, and ACS with TCFA from those without.

Comparison of sLOX-1, hs-CRP and hs-TnT levels among plaque rupture, non-rupture and control.

Elevated Levels of Systemic Pentraxin 3 Are Associated With Thin-Cap Fibroatheroma in Coronary Culprit Lesions

Assessment by Optical Coherence Tomography and Intravascular Ultrasound

Seiji Koga, MD,* Satoshi
Masayoshi Takeno, MD,*
Hiroaki Kawano, MD,* K

Nagasaki and Tokyo, Japan

Objectives This study sought to determine whether systemic levels of pentraxin 3 (PTX3), a novel inflammatory marker, are associated with thin-cap fibroatheroma (TCFA).

Background Biomarkers predicting the presence of TCFA in vivo have not been established.

Methods We evaluated 75 patients (stable angina pectoris, n = 47; acute coronary syndrome, n = 28) with de novo culprit lesions who were examined by optical coherence tomography and intravascular ultrasound. We defined TCFA as lipid-rich plaque with a fibrous cap <65 μm thick. Systemic levels of PTX3 were compared between patients with and without TCFA.

Results Thirty-eight and 37 patients with and without TCFA, respectively, were identified. Levels of PTX3 were significantly higher in patients with than in those without TCFA ($p < 0.001$) and correlated inversely with fibrous cap thickness ($r = -0.71$, $p = 0.001$) and positively with the remodeling index ($r = 0.25$, $p = 0.037$). Multivariate logistic regression analysis showed that a higher PTX3 level was the most powerful predictor of TCFA (odds ratio: 3.26, 95% confidence interval: 1.75 to 6.05, $p < 0.001$). Receiver-operating characteristic curve analysis showed that >3.24 ng/ml of PTX3 could predict TCFA with 84% sensitivity and 86% specificity.

Conclusions Higher levels of systemic PTX3 are associated with TCFA. Systemic PTX3 levels comprise a useful inflammatory marker that reflects coronary plaque vulnerability. (J Am Coll Cardiol Intv 2013;6:945–54)

Pentraxin-3

ABSTRACT

Background: The addition of highly purified eicosapentaenoic acid (EPA) to statin therapy prevents cardiovascular events. However, the impact of this treatment on vulnerable plaques remains unclear. The aim of this study was to assess the impact of adding EPA to a standard statin therapy on vulnerable plaques by serial optical coherence tomography (OCT).

Methods: Forty-nine non-culprit thin-cap fibroatheroma (TCFA) lesions in 30 patients with untreated dyslipidemia were included. Patients were randomly assigned to EPA (1800 mg/day) + statin (23 TCFA, 15 patients) or statin only (26 TCFA, 15 patients) treatment. The statin (rosuvastatin) dose was adjusted to achieve a target low-density lipoprotein (LDL) level of <70 mg/dL. Post-percutaneous intervention and 9-month follow-up OCT were performed to evaluate morphological changes of TCFAs. The EPA/arachidonic acid (EPA/AA) ratio and pentraxin-3 (PTX3) levels were also evaluated.

Results: Despite similar follow-up LDL levels, the EPA + statin group had higher EPA/AA ratios and lower PTX3 levels than the statin group. OCT analysis showed that the EPA + statin group had a greater increase in fibrous-cap thickness, with a greater decrease in lipid arc and lipid length. Macrophage accumulation was less frequently detected in the EPA + statin group than in the statin group at follow-up. When the patients were categorized according to their follow-up PTX3 tertiles, fibrous-cap thickness showed significant increase, and the incidence of macrophages accumulation decreased with lower PTX3 levels.

Conclusion: The concomitant use of EPA and rosuvastatin may stabilize vulnerable plaques better than the statin alone, possibly by suppressing arterial inflammation.

Effect of EPA & statin on TCFA

Table 2
Blood tests and OCT[a] measurements at baseline and at the 9-month follow-up.

Variables	Baseline			Follow-up		
	EPA + statin group	Statin group	*p*-value	EPA + statin group	Statin group	*p*-value
Blood test						
EPA/AA[b]	0.32 ± 0.15	0.27 ± 0.13	0.37	1.11 ± 0.53	0.42 ± 0.31	0.0001

OBJECTIVES The purpose of this study was to evaluate the effect of statin treatment on coronary plaque composition and morphology by optical coherence tomography (OCT), grayscale and integrated backscatter (IB) intravascular ultrasound (IVUS) imaging.

BACKGROUND Although previous studies have demonstrated that statins substantially improve cardiac mortality, their precise effect on the lipid content and fibrous cap thickness of atherosclerotic coronary lesions is less clear. While IVUS lacks the spatial resolution to accurately assess fibrous cap thickness, OCT lacks the penetration of IVUS. We used a combination of OCT, grayscale and IB-IVUS to comprehensively assess the impact of pitavastatin on plaque characteristics.

METHODS Prospective serial OCT, grayscale and IB-IVUS of nontarget lesions was performed in 42 stable angina patients undergoing elective coronary intervention. Of these, 26 received 4 mg pitavastatin after the baseline study; 16 subjects who refused statin treatment were followed with dietary modification alone. Follow-up imaging was performed after a median interval of 9 months.

RESULTS Grayscale IVUS revealed that in the statin-treated patients, percent plaque volume index was significantly reduced over time (48.5 ± 10.4%, 42.0 ± 11.1%; $p = 0.033$), whereas no change was observed in the diet-only patients (48.7 ± 10.4%, 50.4 ± 11.8%; p = NS). IB-IVUS identified significant reductions in the percentage lipid volume index over time (34.9 ± 12.2%, 28.2 ± 7.5%; $p = 0.020$); no change was observed in the diet-treated group (31.0 ± 10.7%, 33.8 ± 12.4%; p = NS). While OCT demonstrated a significant increase in fibrous cap thickness (140 ± 42 μm, 189 ± 46 μm; $p = 0.001$), such changes were not observed in the diet-only group (140 ± 35 μm, 142 ± 36 μm; p = NS). Differences in the changes in the percentage lipid volume index (−6.8 ± 8.0% vs. 2.8 ± 9.9%, $p = 0.031$) and fibrous cap thickness (52 ± 32 μm vs. 2 ± 22 μm, $p < 0.001$) over time between the pitavastatin and diet groups were highly significant.

CONCLUSIONS Statin treatment induces favorable plaque morphologic changes with an increase in fibrous cap thickness, and decreases in both percentage plaque and lipid volume indexes. (J Am Coll Cardiol Img 2012;5:169–77) © 2012 by the American College of Cardiology Foundation

High-Density Lipoprotein Cholesterol Level Is Associated With Fibrous Cap Thickness in Acute Coronary Syndrome

Yuichi Ozaki, MD; Atsushi Tanaka, MD, PhD; Kenichi Komukai, MD; Kohei Ishibashi, MD; Takashi Tanimoto, MD, PhD; Hironori Kitabata, MD, PhD; Yasushi Ino, MD; Takashi Kubo, MD, PhD; Toshio Imanishi, MD, PhD; Takashi Akasaka, MD, PhD

Background: Although low high-density lipoprotein cholesterol (HDL-C) level has been reported as an independent risk factor for coronary artery disease, few studies addressed the direct relationship between the presence of thin-cap fibroatheroma (TCFA) that is considered as vulnerable plaque in pathology and HDL-C level. The aim of this study was to investigate whether lesion vulnerability is related to HDL-C level in patients with acute coronary syndrome (ACS).

Methods and Results: A total of 261 patients with ACS who underwent optical coherence tomography prior to percutaneous coronary intervention, were enrolled. Patients were divided into a TCFA group (n=124) and a non-TCFA group (n=137). TCFA was defined as a lipid plaque (lipid content in ≥1 quadrant) covered with <70 μm-thickness fibrous caps. There were no differences in patient characteristics and clinical results between the 2 groups except for HDL-C level, low-density lipoprotein cholesterol (LDL-C) level, and high-sensitive C-reactive protein (hs-CRP) level. On multivariate regression analysis, low HDL-C level (β coefficient: 0.302, P<0.001), high LDL-C level (β coefficient: −0.172, P=0.008), hs-CRP level (β coefficient: −0.145, P=0.017), and current smoking (β coefficient: −0.124, P=0.028) were identified as independent contributors to fibrous cap thickness.

Conclusions: HDL-C is correlated with fibrous cap thickness of the culprit lesion in patients with ACS. HDL-C may be considered as a therapeutic target for plaque stabilization. (*Circ J* 2013; **77:** 2982–2989)

Objectives The aim of this study was to evaluate the relationship between cholesterol metabolism and coronary plaque vulnerability.

Background Cholesterol homeostasis, defined as the balance between absorption and synthesis, influences the progression of coronary atherosclerosis.

Methods Consecutive stable angina pectoris patients (N = 80) not receiving any lipid-lowering therapy were divided into 2 groups based on the presence of in vivo thin cap fibroatheroma (TCFA) in de novo target vessels assessed by the combined use of virtual histology intravascular ultrasound and optical coherence tomography.

Results Patients with in vivo TCFA (n = 42) showed a higher campesterol-to-lathosterol ratio (3.36 [interquartile range, 2.10 to 4.26] vs. 1.50 [1.20 to 2.50], $p < 0.0001$). The campesterol-to-lathosterol ratio, low-density lipoprotein (LDL) cholesterol, and high-sensitivity C-reactive protein (hsCRP) were positively correlated with the percentage of necrotic core volume ($r = 0.520$, $p < 0.0001$; $r = 0.520$, $p < 0.0001$; and $r = 0.539$, $p < 0.0001$, respectively) and negatively correlated with thinnest fibrous cap thickness ($r = -0.566$, $p < 0.0001$; $r = -0.530$, $p < 0.0001$; and $r = -0.358$, $p = 0.007$, respectively) . The independent predictors of the incidence of TCFA were the campesterol-to-lathosterol ratio (odds ratio: 3.989, 95% confidence interval: 1.688 to 9.428; $p = 0.002$), LDL cholesterol (odds ratio: 1.425, 95% confidence interval: 1.023 to 1.985; $p = 0.03$), hsCRP (odds ratio: 1.025, 95% confidence interval: 1.003 to 1.047; $p = 0.02$), and the percentage of necrotic core volume (odds ratio:1.084, 95% confidence interval: 1.012 to 1.161; $p = 0.02$).

Conclusions Enhanced absorption and reduced synthesis of cholesterol may be related to coronary plaque vulnerability. (J Am Coll Cardiol Intv 2013;6:746–55)

Vulnerable Plaque Detection:
Between Biological & Morphological (OCT) Approach

- Not only the presence of TCFA but also the amount of plaque burden, MLD, MLA, the presence of thrombus, etc. would improve to detect vulnerable plaque.
- Biological inflammatory markers, such as hs-CRP, various type of cytokines, etc. may allow us to support in identifing VP more correctly in addition to plaque characteristics.
- Making score by using several biological inflammatory markers in addition to plaque characteristics may lead us identification of vulnerable plaque much more correct and easier.
