- **PCI**
 - **Culprit of the culprit**
 - **Acute results**
 - **Complications**
- **Vulnerable plaque**
- **Limitations**

- 72 year old female with diabetes and hypertension presented with 3 hours of chest and transient complete heart block
- Medication during transfer to hospital (40km) included aspirin 300mg, clopidogrel 600mg, heparin 400IU, abciximab (bolus).
- Chest pain resolved at the time of admission
- ECG showed ST elevation in II, III, and aVF and ST depression in I, aVL, and V2-V3

ACS; Baseline angiography pre thrombectomy

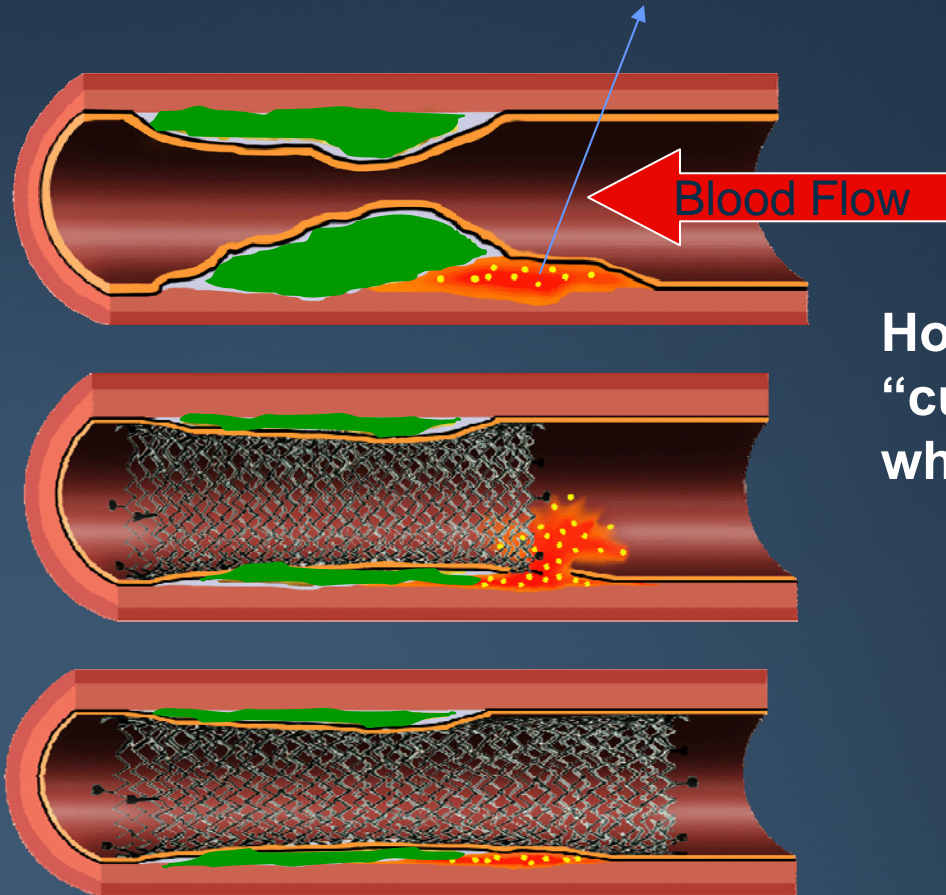

Post-thrombectomy
TIMI 3

Post stenting

Possible Stent Positioning in Culprit Lesion PCI

NC, the “culprit of the culprit”

How often do we miss the “culprit of the culprit”? And what is the impact on

- Distal embolization
- Stent thrombosis
- Restenosis
- Plaque progression

444 ACS culprit lesions entirely imaged using post-stent VH-IVUS (The remaining patients were excluded because of incomplete imaging of stented lesion or unreliable pullback.)

TCFA behind stent (n=259)

No TCFA behind stent (n=185)

TCFA behind stent with reference TCFA that was fully or partially uncovered (n=98)

•No NC at all

•ThFA behind Stent

•Non-classifiable (Stent artifact)

Edge TCFA partially uncovered (n=20)

TCFA behind stent with fully uncovered reference TCFA (n=78)

TCFA only behind stent (n=161)

No TCFA behind stent with fully uncovered reference TCFA (n=33)

No TCFA behind stent w/o reference TCFA (n=152)

NC protruding through stent (n=63)

Predictors of DES Thrombosis & Restenosis

High Risk Plaque

CARDIOVASCULAR RESEARCH
FOUNDATION

COLUMBIA UNIVERSITY
MEDICAL CENTER

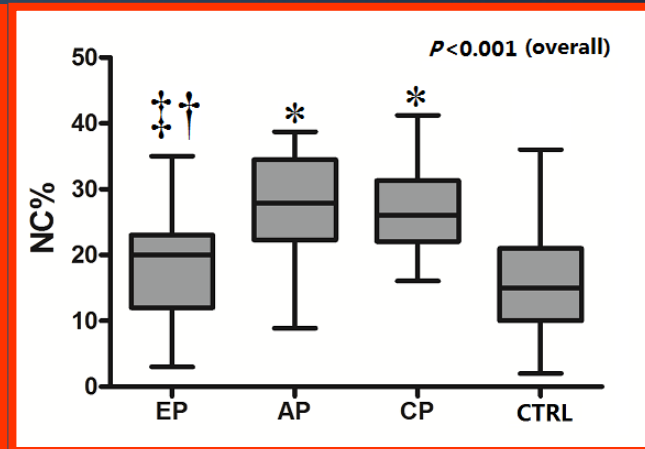

Attenuated Plaque

- Attenuated plaques were observed in 39.6% of STEMI, 17.6% of NSTEMI, and 0% of stable angina.
- Attenuate plaques were associated with more fibroatheromas and a larger necrotic core (on VH-IVUS).
- In ACS patients with attenuated plaques (1) the level of CRP was higher, (2) angiographic thrombus and initial coronary flow <TIMI 2 were more common, and (3) no-reflow or flow deterioration post-PCI were more common.

Attenuated Plaque & Necrotic Core

Courtesy Dr. Simon Dixon
Beaumont Hospital,
Royal Oak, MI

Numerous studies have shown a relationship between VH-IVUS plaque composition and post-PCI distal embolization

vs Nectoric Core

- Kawaguchi et al. J Am Coll Cardiol. 2007;50:1641-6
 - ST re-elevation in 71 pts with STEMI
- Kawamoto et al. J Am Coll Cardiol. 2007;50:1635-40
 - Doppler FloWire high intensity transit signals in 44 pts undergoing elective stenting resulting in poor recovery of CVFR
- Park et al. VH Summit 2007 (unpublished)
 - Largest NC independent predictor of CK-MB release (n=332)
- Hong et al. J Am Coll Cardiol Img, 2009;2:458-468
 - Troponin post elective stenting in 80 pts (29 stable and 51 unstable angina)
- Bose et al. Basic Res Cardiol 2008;103:587-97
 - CK and Tnl in 55 pts undergoing direct stenting. Patients in the 4th quartile of NC volume had a particularly high increase in biomarkers.
- Higashikuni et al. Circ J 2008; 72: 1235-41
 - No reflow in 49 pts with ACS undergoing PCI
- Hong et al. Eur Heart J, in press
 - No reflow in 190 pts with ACS undergoing stenting

vs Fibrotic or Fibrofatty Plaque

- Bae et al. Heart. 2008;94:1559-64.
 - Multivariate analysis revealed that fibrofatty volume over the entire lesion length was the only independent predictor for slow flow during primary PCI in 57 pts with STEMI
- Nakamura et al. J Interv Cardiol. 2007;20:335-9
 - “Marble”-like image, mainly consisting of fibrofatty and fibrous plaque was associated with angiographic no-reflow in 50 STEMI pts undergoing primary PCI

Pathological Atherosclerosis Classification

Terms for Atherosclerotic Lesions in Histological Classification		Other Terms for the Same Lesions Often Based on Appearance to the Unaided Eye	
Type I lesion	Initial lesion	Fatty dot or streak	Early lesion
Type II lesion			
IIa	Progression-prone type II lesion		
IIb	Progression-resistant type II lesion		
Type III lesion	Intermediate lesion (preatheroma)		
Type IV lesion	Atheroma	Atheromatous plaque, fibrolipid plaque, fibrousplaque, plaque	Advanced lesions, raised lesions
Va	Fibroatheroma (type V lesion)		
Vb	Calcific lesion (type VII lesion)		
Vc	Fibrotic lesion (type VIII)		
Type VI lesion	Lesion with surface defect and/or hematoma/hemorrhage and/or thrombotic deposit	Complicated lesion, complicated plaque	

PROSPECT VH-IVUS Classification

Thin-cap FA

Thick-cap FA

PIT

Fibrous

Fibrocalcific

Confluent NC > 10%

30° NC abutting the lumen in
3 consecutive frames
(=1.5mm in length)

CARDIOVASCULAR RESEARCH
FOUNDATION

COLUMBIA UNIVERSITY
MEDICAL CENTER

Because of the resolution of IVUS, diagnosis of a thin fibrous cap is inferred by the contact of necrotic core with the lumen – regardless of the technology

Thin Cap

Thick Cap

- Pathologic thin fibrous cap typical of TCFA is $<65 \mu$
- However, all fibrous caps $<200 \mu$ will abut the lumen on VH-IVUS analysis

PROSPECT: Imaging Summary

Virtual histology
(N=2811 lesions in 611 pts)

- Mean plaque composition-

- Dense calcium
- Fibrotic
- Fibrofatty
- Necrotic core

Plaque subtype	N=2811
Fibrotic	2.5%
Fibrocalcific	1.2%
PIT	35.9%
Fibroatheroma	57.4%
- Thick cap	36.2%
- VH-TCFA	18.9%
- Single, - Ca	5.2%
- Single, + Ca	0.5%
- Multiple, - Ca	9.5%
- Multiple, + Ca	6.1%

Independent predictors of patient level events by Cox Proportional Hazards regression

<u>Variable</u>	<u>HR [95% CI]</u>	<u>P value</u>
Insulin dependent diabetes	3.32 [1.43, 7.72]	0.005
Prior PCI	2.03 [1.15, 3.59]	0.02

Variables entered into the model: age, gender, hypertension, insulin dependent diabetes, prior PCI, CRP at baseline, family history

Independent predictors of lesion level events by Cox Proportional Hazards regression

<u>Variable</u>	<u>HR [95% CI]</u>	<u>P value</u>
$PB_{MLA} \geq 70\%$	5.03 [2.51, 10.11]	<0.0001

Per patient incidence of VH-TCFAs

49.8% of patients have ≥ 1 VH-TCFA

0.95 ± 1.29 VH-TCFAs per patient

(range 0 – 7 per patient)

Total of 581 VH-TCFA lesions in 614 patients

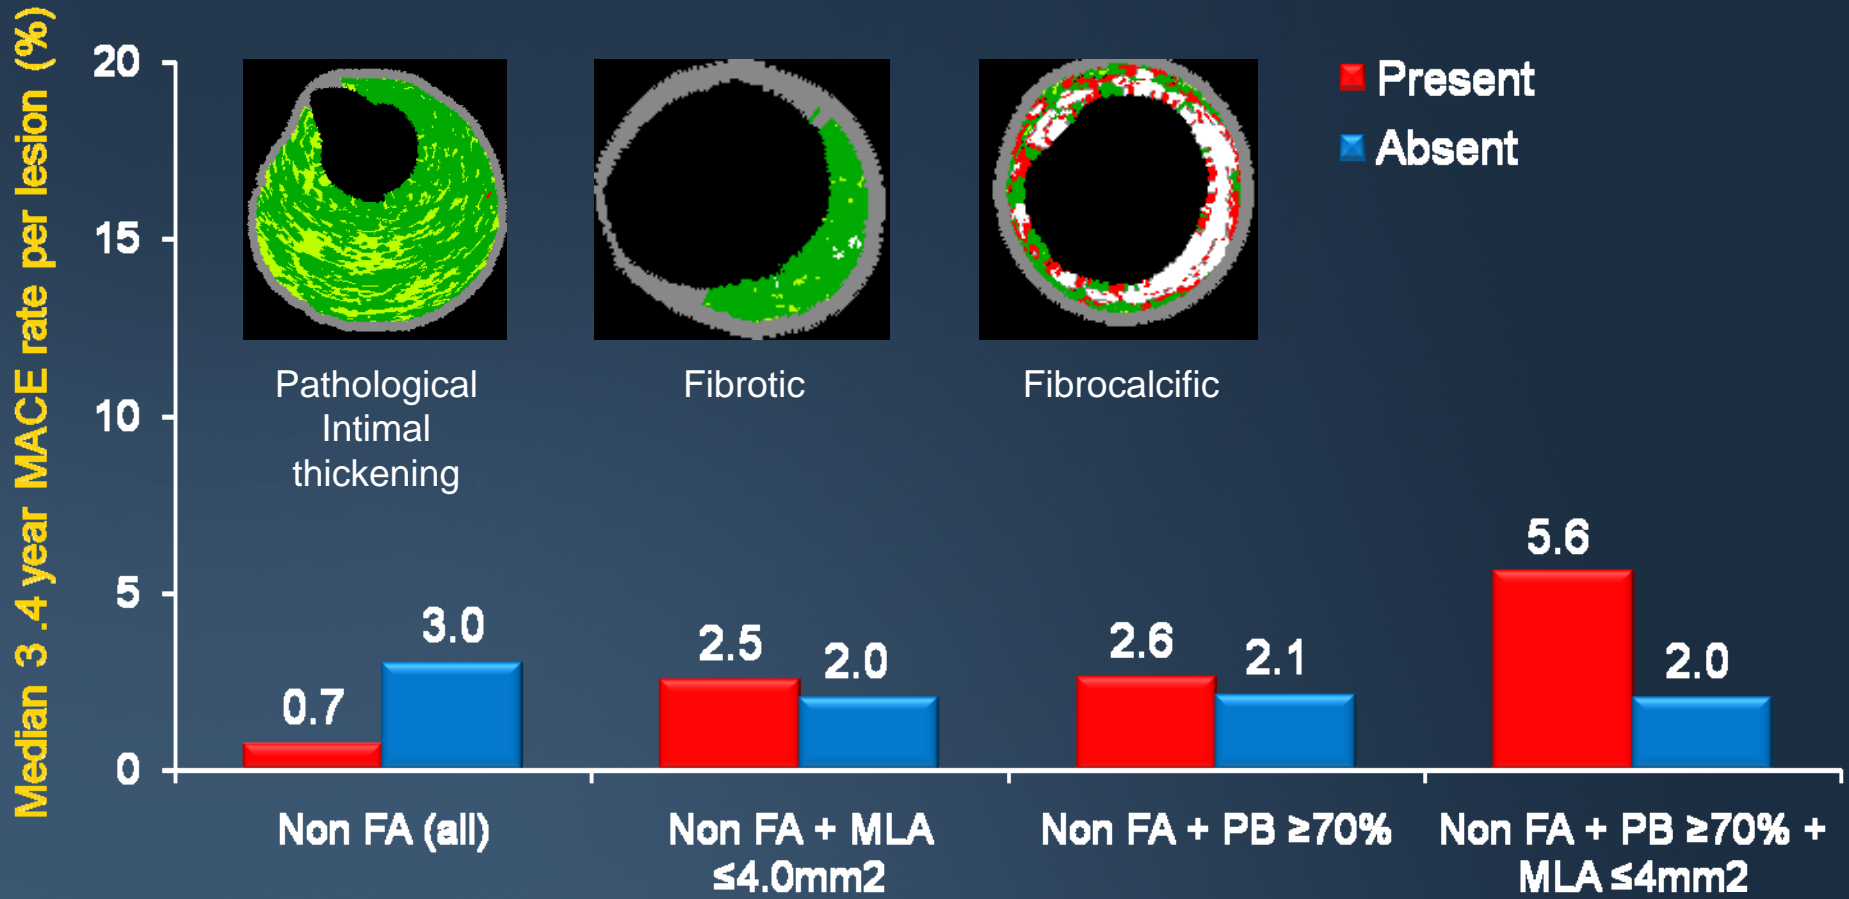

Thick-cap FA and Non Culprit Lesion Events

ThCFA ThCFA + MLA $\leq 4.0\text{mm}^2$ ThCFA + PB $\geq 70\%$ ThCFA + PB $\geq 70\%$ + MLA $\leq 4.0\text{mm}^2$

Lesion HR	0.92 (0.52, 1.63)	3.41 (1.75, 6.65)	5.17 (2.59, 10.32)	5.02 (1.99, 12.63)
P value	0.77	0.0003	<0.0001	<0.0001
Prevalence*	67.6%	22.7%	15.6%	8.3%

Non Fibroatheromas and Non Culprit Lesion Events

Lesion HR	0.22 (0.10, 0.49)	1.22 (0.44, 3.39)	1.25 (0.17, 9.01)	2.60 (0.36, 18.84)
P value	0.0002	0.70	0.83	0.34
Prevalence*	67.9%	19.7%	5.6%	2.7%

Limitations – I: Thrombus

- **Thrombus was detected in 81 of 259 histology slices. Thrombus was colored as fibrous or fibrofatty by VH-IVUS.**
 - Nasu et al Am J Cardiol 2008;101:1079-83
- **As a result. . .**
 - **Superficial thrombus will cause a TCFA to be classified as a ThFCA**
 - **A thrombus-containing lesion may be classified as PIT or fibrotic (stable) rather than unstable**
- **In all probability RF-IVUS detection of thrombus will not be possible by any technique since the IVUS signal changes with the “age” of the thrombus**

Red Thrombus

Sensitivity = 95%

Specificity = 88%

Positive predictive value = 86%

Negative predictive value = 95%

White Thrombus

- There were no significant differences in the peak intensity of the OCT signal between red and white thrombi.
- The OCT signal attenuation of red thrombus was significantly more rapid than that of white thrombus.

Limitations – II: Plaque behind Calcium

- 80% of regions of interest behind calcium contained a distinct low-amplitude signal that had a coherent periodic pattern on adjacent scan lines and a signal increase in the region of the adventitia indicating that this signal contained reflected ultrasound information as well as noise
- 20% of the regions of interest behind calcium had only noise
- Nevertheless, the signal level observed behind calcium is often very close to the noise level. Spectral assessment at such low signal-to-noise ratio might be unreliable, and VH data should be masked when a strong signal is followed by a very low intensity one or the algorithm should report a lower confidence (ala iMAP).

VH-IVUS and Plaque Behind Calcium

- Using the 20MHz transducer, 80% of regions of interest behind calcium contained reflected ultrasound information as well as noise although the signal-to-noise ratio was low. 20% of the regions of interest behind calcium had only noise
(Tanaka et al. J Am Coll Cardiol 2007;49:29B)
- When inaccurate, tissue is classified as NC 65% of the time, FT 18% of the time, and FF 14% of the time (Vince. Volcano Corp)

		Correct	Incorrect	ROIs	Accuracy
Mild microcalcium	IVG	2	0	2	100%
	S5	1	1	2	50%
Heavy microcalcium	IVG	3	6	9	33.3%
	S5	18	9	27	66.7%
Dense calcium	IVG	27	10	37	73%
	S5	27	16	43	62.8%
Overall	IVG	32	16	48	66.7%
	S5	46	26	72	63.9%

Overall Accuracy: 65.0 %

Correlation between VH-%NC and LCBI-NIRS

All Plaques

Non-calcified plaque

Limitations – III: Others

- All tissue between lumen and vessel borders must be classified as one of the four tissue types and VH analysis depends on accurate borders.
- Stent metal appears as calcium surrounded by necrotic core even when implanted acutely (Kim et al. Am J Cardiol 2008;102:1182-6). Should not be interpreted as inflammation.
- No validation for intimal hyperplasia

Border Definition

All tissue between lumen and vessel borders must be classified as one of the pre-defined tissue types
