## Editorial

### Paradigm Has Already Shifted to Ischemia-Guided Functional Approach

Seung-Jung Park, MD, PhD; Young-Hak Kim, MD, PhD

The anatomic Synergy Between Percutaneous Coronary Intervention With TAXUS and Cardiac Surgery (SYNTAX) score is a stratification score illustrating the complexity of angiographic stenosis. It was considered a surrogate for poor prognosis after percutaneous coronary intervention (PCI).<sup>1</sup> Accordingly, in patients with a high baseline SYNTAX score (bSS) requiring coronary revascularization,

analysis of the SYNTAX study by Farooq et al<sup>2</sup> in this issue of *Circulation* provides important information on whether the rSS has a good discriminatory power for predicting outcomes in patients presenting with relatively stable symptoms. Patients with an rSS of >8 had a higher risk of 5-year mortality (35.3%) than those with an rSS of 0 (8.5%), >0 to 4 (8.7%), and >4 to 8 (11.4%). Given these findings, rSS appears to be

REVIEW

### Ischemia-Guided Percutaneous Coronary Intervention for Patients With Stable Coronary Artery Disease

Young-Hak Kim, MD, PhD; Seung-Jung Park, MD, PhD

Current evidence and guidelines support the strategy of ischemia-guided revascularization for treatment of patients with stable coronary symptoms. However, anatomical stenosis is often targeted in revascularization treatment using percutaneous coronary intervention or coronary artery bypass surgery without seriously considering objective evidence of myocardial ischemia. Particularly, for patients with multivessel disease, angiographic complete revascularization was traditionally considered an ideal objective of revascularization treatment. Recently, however, observational studies contradict the concept of angiographic complete revascularization and support the benefit of ischemia-guided selective revascularization based on noninvasive and invasive functional evaluation detecting ischemia-producing coronary lesions. In the absence of a trial specifically designed to assess the relative benefit of either strategy, the present review explores the current concepts about the strength and weakness of anatomical vs. functional revascularization. (Circ J 2013; 77: 1967–1974)

# What is the best tool to detect ischemic lesion and vessel ?

- **Noninvasive method**
  - SPECT
  - PET
  - MRI
  - CT

Relatively high F(-) rate in multivessel and LM disease due to the balanced ischemia, low spatial resolution
- **Invasive method**
  - FFR

# CT-based Functional Imaging

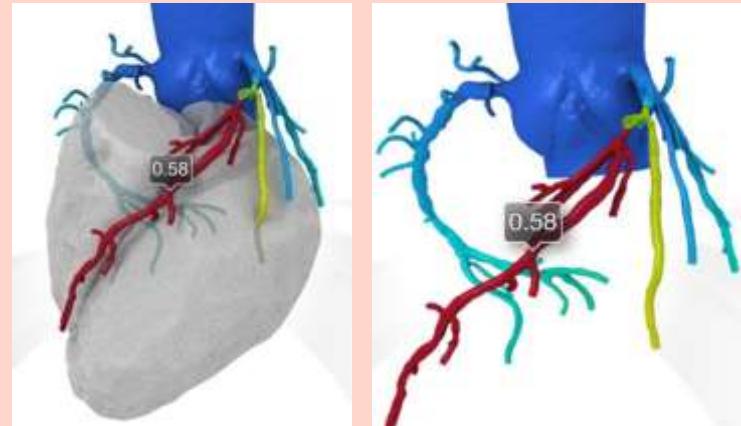

## CT Perfusion (CTP)

- Pros**
- ✓ Direct view of myocardium
  - ✓ Easy to perform
  - ✓ No special software

- Cons**
- ✓ Radiation dose concern (two scans; stress + rest)
  - ✓ Requirement of adenosine

Computational fluid dynamics simulation

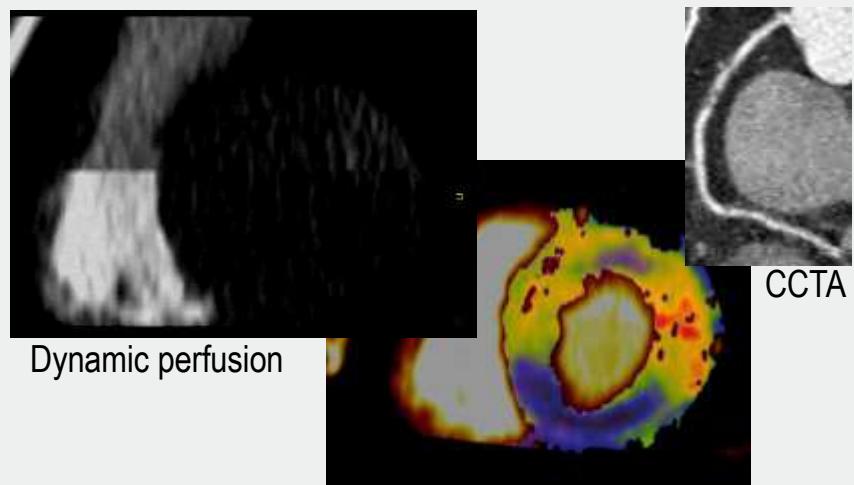

## FFR-CT

- Pros**
- ✓ No additional scan
  - ✓ No requirement of adenosine

- Cons**
- ✓ Indirect view of ischemia
  - ✓ Need supercomputer
  - ✓ No information on perfusion.

# Conclusions

- With technology improvement, CT-based functional imaging become a new feasible method to detect myocardial ischemia.
- CTP showed a good diagnostic accuracy for detection of myocardial ischemia even in patients with severely calcified coronary lesions, which is hardly evaluated using CT angiography or FFR<sub>CT</sub>.
- Further researches are required to improve the performance of CT-based ‘one-stop’ coronary imaging using CTA, CTP and FFR<sub>CT</sub>.
- Ongoing RCT will provide the clinical relevancy of CTP in the diagnosis and treatment of stable coronary artery disease compared with invasive functional evaluation of FFR.
